The control of narcotic drugs had become such a difficult problem that a special committee had represented the Association in a conference on the subject; its report occupies some ten pages of THE JOURNAL. This report condemned the ambulatory treatment of narcotic addiction, recommended that heroin be eliminated from all medicinal preparations and urged intensive action by the government to control narcotics.

A LAY MEDICAL JOURNAL

At the meeting of the House of Delegates in 1920 a resolution was offered to establish a lay medical journal. The House recommended postponement.

MORE SOCIAL INSURANCE

Several resolutions from New York condemned compulsory health insurance and any system which would provide for medical service to be rendered contributors or others provided, controlled or regulated by the federal or state government. These resolutions were supported by Illinois and Michigan.

ENDOCRINE PRODUCTS

For the first time there came a resolution demanding some sort of control over the sale of endocrine products.

The Ad Interim Committee, at the request of the Surgeon General, had tried to work out a technic for reconsideration of the medical service in World War I and leading toward the development of the Walter Reed Hospital as a medical education center.

SOCIAL SICKNESS INSURANCE CONDEMNED

When the Reference Committee on Hygiene and Public Health, headed by Dr. J. W. Schereschewsky of the U. S. Public Health Service, made its report, it submitted the following resolution, which was adopted:

> *Resolved*, That the American Medical Association declares its opposition to the institution of any plan embodying the system of compulsory contributory insurance against illness, or any other plan of compulsory insurance which provides for medical service to be rendered contributors or their dependents, provided, controlled or regulated by any state or the federal government.

That policy has remained the policy of the American Medical Association since 1920.

Significant of the elections held at the end of the 1920 session were the unanimous choice of Hubert Work, speaker of the House, as President and the election as the second speaker of the House of Dr. Dwight H. Murray of Syracuse, N. Y.; the latter had long been active in the affairs of the Association.

Again the Association adopted a resolution urging a national department of health.

WHISKY QUESTION LAID ON THE TABLE

Toward the end of the 1920 session a resolution came from the Council on Health and Public Instruction to the effect that the House of Delegates reaffirm a resolution adopted in 1917 that whisky is not necessary for the proper scientific treatment of influenza. This received a tremendous debate and ended by being laid on the table.

THE JOURNAL COSTS

In November a special session of the House of Delegates met to consider the problem of increasing costs in publication of THE JOURNAL. Statements were made by the editor and by Dr. Frank Billings as secretary of the Board of Trustees. Dr. C. J. Whalen, Illinois, and Dr. W. B. Small, Iowa, were the only two delegates opposed to raising the price of THE JOURNAL, and the action was carried overwhelmingly.

AND AGAIN THE LAY JOURNAL

Under the leadership of Dr. Wendell C. Phillips of New York a movement was begun to promote the establishment of a journal for the public in order to disseminate knowledge of scientific medicine and also to employ a field secretary who would carry on the extension of organizational work.

1921

BOSTON; THE CULTISTS' MENACE

Early in 1921 the rise of antivivisectionists, chiropractors, osteopaths and other nonmedical cultists began to give concern not only to the American Medical Association but to many of the foundations prominent in the field of public health. Arrangements were made for a dinner in New York City, attended by representatives of all these foundations, for a general consideration of the subject. It was felt inadvisable that there be any concerted action in this regard, although it was felt also that there ought to be some definite steps taken to enlighten the public regarding the menace of these cults.

In his first official address as speaker of the House of Delegates Dr. Dwight H. Murray of Syracuse urged particularly the establishment of a journal in the field of public health. He thought it possible that the Association might cooperate with the U. S. Public Health Service in such a publication. He believed that it might be possible to publish a periodical of this type as a Sunday magazine with the newspapers and to include questions and answers. He urged the appointment of field secretaries and a mechanism for presenting to the state medical societies the activities of the American Medical Association. His views were reenforced by similar statements from Dr. Hubert Work as President of the Association.

The report of the Board of Trustees gave much attention to the rehabilitation of veterans.

The Council on Health and Public Instruction had held a conference dealing with the provision of medical care particularly in rural areas. It recognized the need for more study and greater cooperation and requested authorization from the House of Delegates to call a national conference on the subject.

An extensive report dealt with the attitudes of the medical profession relative to narcotic drugs, and an even more extensive report concerned the building of hospitals for the indigent.

The Council on Medical Education and Hospitals was also much troubled by such problems as the training of specialists in contrast to the training of general practitioners, and the chairman of the Council was especially disturbed by what he called "outside interference with medical education." He said:

> I refer to the introduction of a scheme of organization of the faculties of our medical colleges which has been introduced by great educational foundations and by some of the state universities.

And particularly was he concerned with "the plan of all-time clinical instruction." He continued:

> This plan did not originate in the medical profession. It originated outside the medical profession, and unfortunately it has been forced on the situation largely by money. It is a subsidized plan which has been presented to universities with the statement that they would be given one or two millions of dollars or more, provided they would adopt the all-time clinical plan in their scheme of organization. To be sure, the originators of the plan have presented it as an experiment, but it has not been a fair experiment. A scientific experiment necessarily requires a control. There has been no control here. If, on the contrary, the great foundations would take three schools and give each of them two millions or five millions of dollars and put them on the all-time clinical plan, and another three schools of the same caliber and give each of them the same amount of money and allow them to develop under some plan which has been the outcome of the experience of medical educators the world over, the plan that one might refer to as the Trousseau plan, the Billroth plan, the Osler plan, a plan that has developed from the practical experience of medical educators, it would then be a fair experiment. So far the plan has been introduced at Johns Hopkins and Yale, at Washington University in St. Louis, and it has been adopted by the University of Chicago and by Columbia University. I believe also the new university of Rochester contemplates adopting it, and the plan in a somewhat modified way has been adopted by some of the state universities, notably the University of Michigan.

After this preliminary statement, the chairman said that he was opposed to state medicine but he recognized the necessity for organizing the delivery of medical service for wider distribution and lower costs. His report included this conclusion:

> There is special need that the medical profession develop some method by which the great possibilities of modern medicine, in the way of diagnosis, treatment and prevention of diseases, may be brought within the reach of all people. This function, it is believed, should be performed by the medical profession and not through any form of state medicine.

Under "New Business" came a group of resolutions on state medicine reaffirming the point of view previously adopted on this subject. The question was considered so fundamental to the future of the American Medical Association that it was considered by the entire House of Delegates as a committee of the whole. The reference committee suggested, as a substitute for all these resolutions:

> *Resolved,* By the House of Delegates of the American Medical Association, that it approves and endorses all activities and policies of states directed to the prevention of disease but opposes the state treatment of disease, except (*a*) in the institutional care of the delinquent, diseased and defective; (*b*) the treatment of those diseases whose treatment is essential to prevention; (*c*) the recognition and securing the correction of common defects of school children.

However, the committee of the whole made the following substitution, which was unanimously adopted:

> *Resolved,* By the House of Delegates of the American Medical Association that it approves and endorses all proper activities and policies of state and federal governments directed to the prevention of disease and the preservation of the public health.

A SECTION ON ANESTHESIA

Resolutions were offered requesting a section on anesthesia.

FULL TIME TEACHING

The reference committee on medical education refused to take a stand on the question of full time versus part time clinical teaching but suggested that experimentation should provide just as much funds in support of one as of the other.

THE LAY JOURNAL

A half dozen resolutions supported the proposal for a periodical in the field of public health, and the entire matter was referred to the Board of Trustees. Other proposals urged extension of the work of the field secretary as well as of full time paid secretaries for state medical societies.

STATE MEDICINE

Now for the first time came before the House of Delegates a definition of the term "state medicine." One of these, emanating from Dr. W. S. Rankin of North Carolina, included eight different types of legislation which had to do in any way with the relationship of the physician to the state. Another, exceedingly brief, came from a New York delegate, Dr. E. F. Delphey, which said succinctly:

> *Resolved,* That the term "State Medicine" be defined by this Association as the practice of medicine by the state by physicians on a salary to the exclusion of all other and individual practice of medicine.

Then came another definition by Dr. James F. Rooney of New York:

> *Resolved,* That the American Medical Association defines "State Medicine" to be any method providing for the practice of medicine under the direction, subsidy or control of the state or national government, excepting those functions having to do with preventive medicine and public health which do not involve the treatment of disease except that which is communicable.

The session of the American Medical Association on June 9, 1921 witnessed one of the peculiar personal attacks which has occurred at fairly frequent intervals in the House of Delegates—this time concerning one of the greatest leaders in the history of American medicine. The man involved was Dr. Frank Billings, and the attack on him was apparently led by Dr. E. H. Ochsner of Illinois. Through some means, not clearly defined, a circular quoting a statement alleged to have been made by Dr. Billings and published in the *American Labor Legislation Review* in 1917 was widely circulated in the House of Delegates. In this statement Dr. Billings was reported to have said that he was "unequivocally in favor of compulsory insurance and the protection of maternity." In 1921 Dr. Billings had published a statement recommending the growth of health centers, which were attacked in the circular as being "the shortest route possible to state medicine." Following this attack, Dr. Frank Billings addressed the House of Delegates. He told the circumstances under which the statement alleged was made and pointed out that it might have been an inaccurate report from a conference held in Washington in 1916. Dr. Billings said:

> Since that time I have declared in published articles that compulsory health insurance was not applicable to the United States, and that I am opposed to it, and that state medicine as related to the treatment of disease I look on in the same way.

Dr. Billings recognized that the attack made on him was in effect a charge of duplicity. He continued:

> I am charged before you and before the profession with writing articles and working for the legal enactment of compulsory health insurance and of state medicine in this country while saying to you and to the profession that I am opposed to it.

He referred to his career in the American Medical Association, including membership in the House of Delegates for eight years, the presidency of the Association and membership on the Board of Trustees since 1918. By unanimous vote the House expressed its confidence in Dr. Billings and referred the circular to the Judicial Council.

THE LAY JOURNAL

The Board of Trustees made a supplementary report that facilities to undertake and publish a health journal would be lacking until the completion of a new building, at which time it proposed to publish such a journal.

COMPOSITION OF THE HOUSE OF DELEGATES

An amendment to the Constitution provided for seating of the trustees and ex-presidents of the Association in the House of Delegates as ex officio members, without the right to vote.

SECRETARY OF HEALTH

Numerous resolutions brought in toward the end of the session dealing with general affairs of the Association were referred to the Board of Trustees, including one which insisted that health should not be submerged in a national department of public welfare but that it have a separate secretary in the cabinet.

ALCOHOL

Again the House of Delegates was concerned with alcohol. One resolution proposed that alcohol be considered a beverage detrimental to the human economy and that its use as a food, tonic or stimulant had no scientific basis and that the Association expressed its disapproval of the acceptance of a small minority of the profession of the position of being purveyors of alcoholic beverages. Another resolution condemned the promiscuous prescribing of alcohol.

The Ad Interim Committee of the Association addressed a message to the President of the United States approving his general attitude toward public welfare and his evident desire to coordinate interdepartmental activities and functions. The committee insisted, however, that there be medical direction in all divisions requiring medical knowledge.

1922

ST. LOUIS

So rapid was the growth of the Association that additions to its buildings had to be considered almost every second or third year. The continuously increasing publications demanded constant supervision, and almost every year the Board of Trustees was compelled to consider changes in the editorial boards because of losses by death or other untoward incident. The growth of the councils required also annual consideration as to changes in membership.

DR. OLIN WEST BECOMES FIELD SECRETARY

With 1922 the general manager, Dr. George H. Simmons, announced that the Board of Trustees, in pursuance of its wish to promote medical organization and medical economics, had secured Dr. Olin West of Nashville, Tenn., then secretary of the Tennessee State Medical Association, to serve as field secretary. He would report in April.

THE ALCOHOL REFERENDUM

So serious had become the debate as to the virtues of alcohol in the treatment of disease that the Board of Trustees had conducted a referendum on the value of alcohol. The Board decided to present to the House of Delegates an abstract of the results of this referendum and with it suggestions for modifications of the Volstead Act which would permit the physician who desired to do so to command a pure drug in the form of whisky or other distilled spirits at a price fixed by the government.

The Association had also conducted negotiations with the commissioner of the Bureau of Internal Revenue on the regulations controlling administration of the Harrison Narcotic Act, with a view to making its administration less onerous to the physician.

ADVERTISING OF COMMERCIAL LABORATORIES

The rise of the commercial clinical laboratories and of fly-by-night postgraduate courses was also giving concern to many agencies interested in standardization of medical science on a high level. It became necessary to adopt regulations governing the advertisements of such institutions.

THE POPULAR JOURNAL

At this time also came debates relative to the popular health bulletin or journal to be published by the Association. The members of the Council on Health and Public Instruction had been requested to submit in writing their concept of such a periodical and its editor, the method of distribution and the prices to be charged for an annual subscription. The opinions were as diverse as the membership itself. Three wanted a magazine that would look like the *National Geographic*. One insisted that the editor be a physician, while the next insisted that the editor be a layman, and still another that he be one experienced in welfare work. Indeed, one member inclined very strongly toward the welfare concept and conceived of a publication in which all national welfare organizations would conduct departments.

A LECTURE BUREAU

With the coming of the new field secretary, it was also proposed that there be established a lecture bureau under his charge and it was agreed that all officers and officials of the Association, as well as the members of the House of Delegates, make their services available to this lecture bureau and that the lecture bureau prepare a syllabus to guide speakers in their presentations.

AMERICAN MEDICAL ASSOCIATION BULLETIN

Next came the question of securing more practical cooperation between officers of county and state societies and the headquarters office. With this object in view, the Board requested the reestablishment of the AMERICAN MEDICAL ASSOCIATION BULLETIN, to be issued as often as once a month for nine months in the year under the editorship of the secretary of the Association and to be devoted wholly to questions of organization and economic, social and ethical questions pertaining to the practice of medicine.

In the meantime the Council on Medical Education and Hospitals was investigating group practice, and the opening of the Cornell Pay Clinic had aroused much disturbance in New York City, which in turn was reflected to the Board of Trustees.

ANNUAL REPORT OF THE BOARD OF TRUSTEES

By this time the work carried on by the Board of Trustees had become so profuse that nearly three hours was required at the meeting of the Executive

Committee of the Board of Trustees for the presentation and discussion of the report to be sent to the House of Delegates.

DR. GREEN RESIGNS

In April 1922 Dr. Frederick R. Green, who had served with the Association so long and in so many different capacities, resigned to become associated with Dr. John Dill Robertson of Chicago in the publication of a health magazine. This action caused some consternation, since he had been serving as secretary of the Council on Health and Public Instruction in a capacity which gave him intimate knowledge of the plans of the American Medical Association to publish a similar periodical. The periodical jointly produced by Drs. Robertson and Green suffered a short and financially disastrous career. The publication begun by the Association and eventually named HYGEIA had in 1947 reached its twenty-fifth year of existence.

At the meeting of the Board of Trustees previous to the St. Louis session there came a resolution from the Council on Health and Public Instruction which was to create much concern in ensuing years. It dealt with the prevention of conception and proposed that the American Medical Association take action to secure modification of federal laws which interfered with the right of the physician to give advice by mail on this subject. The Board of Trustees decided at that time that the question was one on which it could not take action.

THE TREASURER

At this meeting of the board Dr. William Allen Pusey, who had served with distinction as treasurer, resigned and was succeeded by Dr. Austin A. Hayden.

ST. LOUIS SESSION

When the House of Delegates convened in St. Louis in May the speaker of the House of Delegates, Dr. Frederick C. Warnshuis, made an address devoted to such topics as education of the public regarding scientific medicine, which discussion he concluded with numerous recommendations regarding the work of the Council on Health and Public Instruction. He discussed compulsory health insurance, asserting that it "never will and never can become an American institution." He considered the trained nurse and nursing problems and recommended that "our Association should assert itself in formulating an acceptable status for the trained nurse and the educational fundamentals requisite for her work of service." He proposed a semiannual meeting of the House of Delegates—a suggestion which was adopted in 1946. He concluded his address with a recommendation that all legislative activities of the American Medical Association be placed in the Council on Health and Public Instruction and that a legislative bureau be established in the headquarters office.

ADDRESS OF DR. WORK

The President of the Association, Dr. Hubert Work, followed with an address in which he pointed out the importance of close liaison between the American Medical Association and state societies. He felt that the councils should be increased in number and most of their work placed on the secretaries. Of organization, he said:

> Periodically the Association is criticized by one, or a small group of members, apparently actuated by destructive motives veiled by a demand for reorganization. The charges are usually built around the complaint that the Association is dictated by a few men in their own interests.

"Part of this statement is true," he said, and then he continued:

> This Association, and all others, even the national government, is directed by a few men for the principal reason that there is no other way to do it. That it is run in the interests of these few men is not true unless the expenditure of time, thought and money, with neglect of personal business, may be so construed. It has uniformly happened that those who have tried to break in, by first breaking down, have been members who have done nothing to build up.

On the subject of state medicine he made a few profound observations:

> The public is entitled to know the legitimate limitations of a state's participation in the practice of medicine. . . . Promiscuous medical treatment of disease . . . is not a state's function, and interference with it through any unit of government should not be tolerated by the public or by physicians. . . . The practice of medicine must remain a process of personal contact, invoking the patient's right of selection and the direct moral responsibility of the physician, with a sympathetic reaction between the two.

PRESIDENT-ELECT DE SCHWEINITZ

Dr. George E. de Schweinitz reviewed many of the activities of the agencies of the Association, showing a thorough knowledge of the work of the councils. He was much concerned that the views of individual members have opportunity for presentation to the House of Delegates, and he endorsed particularly the desirability of a semiannual session of the House.

BOARD OF TRUSTEES

In its report to the House of Delegates the Board of Trustees noted particularly the financial difficulties related to loss of income by many other periodicals and pointed out that during the period the financial condition of THE JOURNAL had been stable. The Spanish periodical was operated at a loss and also with a limited circulation. The QUARTERLY CUMULATIVE INDEX MEDICUS had met with instant favor. Most important, however, was the report on the construction of the new property.

The Board of Trustees recognized the existence of pay clinics, diagnostic clinics and group practice. The Council on Health and Public Instruction had recorded the existence of 139 group clinics and was making an attempt to determine the scope of their work.

The Judicial Council at this session also entered the arena with an extensive report on advertising medical institutions. The problem had reached them because of the existence of new institutes devoted wholly to the treatment of venereal diseases which were endeavoring to secure patients by advertisements in the press. The Judicial Council unhesitatingly condemned such institutions as being both unlawful, practicing as corporations, and unethical because of the nature of their practice.

The Council on Medical Education also paid its respects to so-called group practice and defined it as "the practice of medicine by an organization of physicians in which each member contributes to the group his professional service and receives from the group certain benefits in return and in which the members unite in the diagnosis of cases that indicate need for their combined service." The Council on Medical Education pointed out that less than 700 physicians in the United States were engaged in such practice and said

"It is notable also that a large number of 'group practices' are rather short lived. At present, therefore, the group practice movement does not seem to warrant any very great concern on the part of the profession."

The Council on Scientific Assembly refused to make any statement on the therapeutic value of alcohol and recommended that the House of Delegates take no action on such a question. As the floor was thrown open to the delegates for the introduction of new business, there came a half dozen resolutions on the prescribing of alcoholic liquors, a new definition of state medicine, and several proposals for changing the Constitution and By-Laws.

There was an attack on the Sheppard-Towner Maternal Welfare Act as a form of federal bureaucratic interference with the sacred rights of the American home. The House of Delegates adopted resolutions condemning the Sheppard-Towner law and also a resolution on the prescribing of alcohol. This resolution indicated that 51 per cent of physicians consider whisky necessary in the practice of medicine and recommended further that provision be made for supplying bonded whisky for medicinal use only at a fixed retail price to be established by the government.

When the reports of the officers were considered, the reference committee approved the establishment of a bulletin as the official journal of the House of Delegates, to be edited by the secretary of the Association, the field secretary and the speaker of the House. It approved a survey of clinics and group practice, approved enlargement of the Council on Health and Public Instruction and a survey of nursing institutions, but it could see no present need of regular semiannual sessions of the House of Delegates.

DEATH OF DR. J. N. MC CORMACK

A special committee had been established to draft a resolution on the death of Dr. J. N. McCormack. He had died on May 4, 1922, at the age of 75. Among other credit given to him was recognition of his magnificent efforts for the organization and reorganization of the American Medical Association and for the fine work that he had done in the state of Kentucky.

> For forty years he gave his time and labor by day and by night to protecting the people from disease and promoting the organization and efficiency of the medical profession.

OVERSPECIALIZATION

The House of Delegates recognized the need for more medical schools. It deplored the tendency toward premature or over rapid specialization. The relationships of the medical school to the university gave them great concern. The House of Delegates believed that it was especially important that teachers in the clinical departments retain their usual relationships to the medical profession.

GROUP CLINICS

To meet the rising threat of group clinics which would secure their patients by advertising in the public press, the Judicial Council had proposed an amendment to the Principles of Medical Ethics dealing with the solicitation of patients by physicians which has been a guiding principle in maintaining an ethical standard since its adoption. This section of the Principles of Medical Ethics merits repetition:

> Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional. This does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated. It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind, or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned. All other like self laudations defy the traditions and lower the tone of any profession and so are intolerable. The most worthy and effective advertisement possible, even for a young physician, and specially with his brother physicians, is the establishment of a well merited reputation for professional ability and fidelity. This cannot be forced but must be the outcome of character and conduct. The publication or circulation of ordinary simple business cards, being a matter of personal taste or local custom, and sometimes of convenience, is not per se improper. As implied, it is unprofessional to disregard local customs and offend recognized ideals in publishing or circulating such cards.
>
> It is unprofessional to promote radical cures; to boast of cures and secret methods of treatment or remedies; to exhibit certificates of skill or of success in the treatment of diseases; or to employ any methods to gain the attention of the public for the purpose of obtaining patients.

WOMAN'S AUXILIARY

From Texas at this session of the House of Delegates came a request that the American Medical Association approve a movement to organize a Woman's Auxiliary to the American Medical Association.

> The object of this auxiliary shall be to extend the aims of the medical profession through the wives of doctors to the various women's organizations, which look to the advancement in health and education; also to assist in entertainment at all medical conventions and to promote acquaintanceship among doctors' families that closer professional fellowship may exist.

This came from the Woman's Auxiliary of the State Medical Association of Texas under the presidency of Mrs. S. C. Red. The House of Delegates approved the resolution. The Woman's Auxiliary thus created had grown by 1947 to a total membership of almost 30,000.

The House of Delegates also urged the Board to proceed as rapidly as possible with its publication of a journal for the public.

SECTION ON MISCELLANEOUS TOPICS

So many specialties had by this time begun to request sections in the Association that the Council on Scientific Assembly had evolved the idea of a special Section on Miscellaneous Topics which would be a tryout area for such new sections. Thus they could hold one or two meetings as the Section on Miscellaneous Topics and when sufficient interest was proved take on the full status of a section.

At this time also the name of the Section on Preventive Medicine and Public Health was changed to the Section on Preventive and Industrial Medicine and Public Health, indicating the new interest that was developing in the field of medical care in industry.

DEFINITION OF STATE MEDICINE

A new definition of state medicine was adopted with the following action:

> The American Medical Association hereby declares its opposition to all forms of "state medicine" because of the ultimate harm that would come to the public weal through such form of medical practice.
>
> "State medicine" is hereby defined for the purpose of this resolution to be any form of medical treatment, provided, conducted, controlled or subsidized by the federal or any state government, or municipality, excepting such service as is provided by the Army, Navy or Public Health Service and that which is necessary for the control of communicable diseases, the treatment of mental disease, the treatment of the indigent sick

and such other services as may be approved by and administered under the direction of or by a local county medical society and are not disapproved by the state medical society of which it is a component part.

DR. WILLIAM C. WOODWARD ADDED

The Board had agreed to accept as the first director of the Bureau of Legal Medicine and Legislation Dr. William C. Woodward, formerly health commissioner of Boston.

HYGEIA

The birth pangs of Hygeia, tentatively known as the people's medical magazine, were a matter of greater travail than was the birth of The Journal of the American Medical Association itself. There was, first, the question as to whether or not it ought to be published under the control of the Council on Health and Public Instruction or under the control of the Board of Trustees. Next came the question as to whether or not participation by the American Public Health Association should be authorized. Among others considered for the editorship was Dr. George Dock.

All the members of the Council had been queried as to their attitudes. Such eminent authorities as Dr. Edwin E. Slosson were consulted. Almost every physician, writer on science or public health official whose name had loomed large in the public prints was suggested as a possibility for the editorship.

AN OSTEOPATHIC CHALLENGE

About this time George A. Still, president of the American School of Osteopathy, proposed a challenge to the American Medical Association for a wager of $5,000. He suggested that a number of patients with pneumonia be selected whom the doctors would treat according to their methods and whom the osteopaths would treat by their technics. As with a football game, he proposed that any time an osteopath gave a drug of any sort it might count like an offside play or "clipping," and the osteopaths would be penalized, whereas the use of manipulations by the doctors would be counted as a penalty against them. "Packs," he suggested, "either as flannel jackets, antiphlogistine or any other physical pack will be allowable by either contestant." It was proposed that three unprejudiced laymen be the umpires. In reply Dr. Simmons called attention to the fact that he would not recommend trifling with human life in the manner proposed in order to determine a wager, and he noticed that the Associated Press had already received the communication of Dr. Still before it reached the American Medical Association office.

DR. VAUGHAN BECOMES AN EDITOR

By August it became apparent that the Board of Trustees had authorized Dr. Victor Vaughan to proceed with the publication of the popular medical magazine and had begun to solicit articles from a number of writers and to plan definitely for the publication.

THE FIELD SECRETARY

Dr. Olin West had begun as field secretary to visit the states needing help in organizational efforts. He had been preparing most of the material that was appearing in the American Medical Association Bulletin. Because of the resignation of Dr. Frederick R. Green, he had been serving also as acting secretary of the Council on Health and Public Instruction. The states had been queried as to their desires in relation to the work of the field secretary.

HYGEIA

By this time it had been determined to name the popular periodical Hygeia. Dr. Vaughan was endeavoring to work out a plan whereby Science Service would cooperate in the publication—a plan which incidentally came to naught. He was being greatly aided by Dr. Edwin E. Slosson with suggestions submitted in writing under the title "Fugitive Hints for Hygeia."

DEATH OF DR. CRAIG

In the period between the August and September meetings of the Board of Trustees Dr. Alexander Craig, secretary of the Association, died rather suddenly. In an attempt to secure a successor, the names of many leading physicians in the United States were considered, including the deans of most of the medical schools.

The new Bureau of Legal Medicine and Legislation was having most of its trouble with the laws regulating the prescribing of alcohol and narcotics and new laws dealing with antivivisection.

The travail of Hygeia continued. Great numbers of prospective editors were considered, including five or six army officers, three or four public health officials, two or three deans, one neuropsychiatrist and a few newspaper men. There were innumerable problems as to whether or not to purchase material, how the magazine could be circulated, whether or not it should be in color and similar questions.

AMERICAN RED CROSS

In the meantime meeting after meeting of the Board of Trustees and of the House of Delegates had been concerned with working out some sort of an arrangement with the American Red Cross which would clearly define the public health and medical functions of that agency. Through the intermediation of Dr. Hubert Work and Dr. George de Schweinitz with Judge Payne, a satisfactory agreement had been reached as to these functions. Recommendations had been made for a medical advisory committee, but at that time nothing serious was done. In fact, medical advisory committees to the American Red Cross were such in name only and without much in the nature of activity until Mr. Basil O'Connor was made national chairman of the Red Cross. He promptly appointed a competent medical advisory committee, which has been associated with him in the medical functions of the Red Cross since his appointment.

Dr. Olin West had been acting as secretary since the death of Dr. Craig, and it was agreed by the Board of Trustees at its last meeting for 1922 that he would be nominated by the Board to the position of secretary.

Special consideration was given to the establishment of Hygeia. By this time Dr. Victor C. Vaughan had determined to act at least temporarily as editor, and he agreed to serve with the understanding that the members of the Council on Health and Public Instruction would be the editorial board but that he should have the cooperation of Drs. Morris Fishbein and Arthur J. Cramp of the headquarters office in the work of editing the publication.

At this time also there came to the Board of Trustees the suggestion that there be a scientific exhibit for the public in connection with each annual session of the American Medical Association. This idea met with scant interest, however.

At the last meeting in 1922 also a proposal was made to provide group insurance for all the employees of the American Medical Association. The proposal went to the Board of Trustees for consideration, but some twenty years passed before this recommendation became effective.

1923

SAN FRANCISCO

With 1923 a reorganization of the Board of Trustees was considered desirable. The three year term and the election of three members annually permitted much instability in the conduct of the affairs of the Association. In the years 1907-1908 five new and inexperienced men were elected to membership on the Board in a period of twelve months. It was therefore recommended that the members of the Board of Trustees be elected to five year terms with a limitation of two terms to any member and that two trustees be elected each year. These recommendations were to be made to the House of Delegates and amendments to the Constitution and By-Laws submitted to make them effective.

At this time Dr. John M. Dodson was selected as secretary of the Council on Health and Public Instruction. Attempts were being made to find a new field secretary to take the place left vacant by the elevation of Dr. Olin West to secretary.

By this time the attempt to secure a secretary of health in the cabinet was again being actively revived. With the aid of Brig. Gen. C. E. Sawyer, who occupied the position of White House physician in the Harding administration, the proposal was being made that there be a single department of education and welfare. It was agreed that the importance of health in the picture be brought to the attention of the Brigadier General.

For some time the Association had been aiding in the reorganization of the Gorgas Memorial Institute in Panama. Now it reached the phase of a request by Dr. Franklin H. Martin to present the plan of reorganization to the House of Delegates.

In 1923 the Veterans Bureau appealed to have its physicians considered in the same relationship to the American Medical Association as were the physicians of the Army and Navy, with a representative in the House of Delegates.

When the Board of Trustees met previously to the annual session of the Association in San Francisco in 1923, several matters of great moment to American medicine came before it. Among the first was a recommendation that the Council on Health and Public Instruction be discontinued and that there be established in its place a bureau on Health and Public Instruction. The Board's attention was called to the fact that the functions on organization, legislation and medicolegal affairs had been distributed to other departments of the Association and that its health education function would be largely conducted through Hygeia. It was therefore suggested that the publication of Hygeia be placed wholly on the Board of Trustees and that the Council be discontinued. The suggestion met with instantaneous approval. The Board of Trustees agreed to formulate the necessary changes in the Constitution and the By-Laws to make this action effective. It was decided to present directly to the House of Delegates the other questions raised in the consideration.

Dr. Ray Lyman Wilbur had been elected President of the Association to succeed Dr. George E. de Schweinitz.

RESIGNATION OF DR. GEORGE H. SIMMONS

In 1923 at the San Francisco session Dr. George H. Simmons submitted his resignation after having served the Association for twenty-five years. He requested that there be no public announcement, so that the Board might have ample time to select a successor.

WARNSHUIS RECOMMENDS

When the House of Delegates met, the speaker of the House, Dr. Frederick C. Warnshuis, called attention to the death of Dr. Alexander Craig on Sept. 2, 1922. He repeated his recommendation for a semiannual session of the House of Delegates. He spoke at great length on the socialization of medicine. He thought it desirable that there be a large committee to consider the question of a national welfare department in the President's cabinet. He paid glowing tribute to the Board of Trustees, and he recommended that the Bulletin of the Association be discontinued and that sufficient space be allotted in The Journal for the necessary organizational material previously published in that periodical. He recommended, as had previous leaders of the Association, the appointment of at least some reference committees thirty days in advance of the annual session so that lengthy reports could be given adequate consideration before the session was held.

PRESIDENT DE SCHWEINITZ COMMENTS

Dr. George E. de Schweinitz paid gracious compliments to the editor and general manager, the Board of Trustees, the Council on Medical Education and Hospitals and other agencies of the Association. He urged that the duties of the President and President-Elect should be more strictly defined. He congratulated the Association particularly on its publication of Hygeia.

DR. WILBUR REMINDS

As President-Elect, Dr. Ray Lyman Wilbur urged the House of Delegates to remember that it was a legislative and not an administrative body. He felt that there should be more long term planning in the Association and that there should be more responsibility placed on the state organizations. Particularly did he urge that the Association participate in the great projects for Russian relief, which at that time were agitating our country.

THE BOARD PAYS TRIBUTE

Without calling to the attention of the House of Delegates the resignation of Dr. George H. Simmons, the Board of Trustees concluded its extensive report on the projects that have already been mentioned with an appreciation. It said:

> For a period of twenty-five years Dr. George H. Simmons has devoted his entire time and energy to service for the Association. The members of the Board are unanimously of the opinion that an expression of appreciation should be made to him at this time. As Editor and Manager, he has manifested remarkable literary ability, and it is due chiefly to his editorial

management that THE JOURNAL is recognized as the foremost general medical publication of the world, with a circulation at home and abroad of 80,000 copies weekly. He has shown rare and efficient administrative skill, which has won the respect and confidence of all the general officers, the members of the Board of Trustees, the members of the councils and committees, the personnel at headquarters, and the Fellows of the Association who have been fortunate enough to come in close contact with him. He has been honest, individually unselfish, loyal, and his efforts have been productive of the greatest service to the Association.

The Council on Health and Public Instruction, in what was to be its swan song, called attention to the various actions which it had taken during the year. It indicated that Dr. John M. Dodson, who had been appointed acting secretary of the Council, was also serving as editor-in-chief of HYGEIA.

BUREAU OF LEGAL MEDICINE

For the first time there came an extensive report of the Bureau of Legal Medicine and Legislation, read by Dr. William C. Woodward as executive secretary, to the House of Delegates at the request of the Board of Trustees. He concerned himself with the manner in which the Bureau had been created. He then discussed the National Prohibition Act and indicated that success had been secured in persuading the Commissioner of Internal Revenue to withdraw from warehouses spirits bottled in bond for medicinal purposes. He discussed the regulations of the Harrison Narcotic Act and the relationship of the Veterans Bureau to the training of chiropractors. The Sheppard-Towner Maternity Act had been enacted by the Congress, and the Bureau had been aiding the medical profession of the individual states where opposition to the act was being developed. That act was before the Supreme Court of the United States for the determination of its constitutionality. He outlined in detail the attempt of Brig. Gen. C. E. Sawyer to develop a national department of education and welfare with the hope that it would be known as the Department of Education, Health and Welfare. This matter in 1947 is still before the Congress, the latest legislation calling for the establishment of a Department of Health, Education and Security. The remainder of his presentation was concerned with legislation in the individual states and with the difficulty of animal experimentation.

The House of Delegates approved the recommendation for the change in the manner of electing trustees, but since this required an amendment to the Constitution, it had to lie over for another year.

THE GORGAS MEMORIAL

In accordance with previous arrangements, Dr. Franklin H. Martin discussed at length the work of the Gorgas Memorial, and the House of Delegates by a rising vote pledged the American Medical Association to do everything in its power to assist the Committee on Gorgas Memorial to erect the building.

PRESCRIBING LIQUOR

Following the action of the Commissioner of Internal Revenue in relation to providing whisky bottled in bond for prescription purposes, a resolution was introduced commending the Association for the Protection of Constitutional Rights, for its public spirited efforts in securing this action; also a resolution that in the judgment of the House of Delegates of the American Medical Association every state and county medical association should use its best endeavors to discipline physicians who were negligently or wilfully prescribing liquor otherwise than in accordance with the law and to purge the medical profession of physicans who wilfully under the cloak of their profession prescribe liquor for other than medicinal purposes.

There was the usual resolution condemning the Volstead Act for interfering with doctors in their practice.

There was an appeal to establish the Section on Radiology.

There was a spirited election in which Dr. William Allen Pusey was elected President over Dr. William D. Haggard by a vote of 66 to 62.

THE EAGLETON RESOLUTION

On the closing day of the session came a resolution from the State Medical Society of New Jersey, under the leadership of its president, Dr. Wells P. Eagleton, requesting the Board of Trustees to disassociate the editorship and general management of the Association, placing the editorship entirely separate from the general management. This communication was referred to the Board of Trustees without objection. The story behind this action is interesting; it may now be told since the two chief characters in the drama are no longer among the living. Dr. Wells P. Eagleton had published a book on the subject of brain abscesses and had requested that the advertisement of that book appear on the front cover of THE JOURNAL. Dr. George H. Simmons had called to his attention the fact that the front cover had been sold under contract to another publisher and that it was not possible to invalidate the contract in order to permit the advertisement of Dr. Eagleton's book. Dr. Eagleton took violent exception to this decision, asserting that the rights of a Fellow of the Association should have precedence over any commercial interest whatever. In proposing the action of the State Medical Society of New Jersey before the House of Delegates, he insisted that THE JOURNAL represent solely the scientific and ethical side of the American Medical Association. He said:

> The editor should devote his entire time to the scientific and ethical aspects of the profession, not to its business.

This step initiated by Dr. Eagleton was to have repercussions for years to come. In 1924 the work of the editor was separated from the activities of the general manager.

ARCHIVES OF OTOLARYNGOLOGY

Following the meeting of the House of Delegates came a proposal for the publication of a journal on otolaryngology, and the Board of Trustees agreed to undertake such a publication.

HYGEIA

In the meantime the Board of Trustees continued to search for an editor for HYGEIA. The editors of leading women's magazines were consulted, and six additional candidates were proposed. Dr. Simmons was convinced that the matter should not be too hastily acted on. He agreed to interview the candidates to aid in making a decision.

LEGAL PROBLEMS

At this time the Bureau of Legal Medicine was conducting discussions with the Commissioner of Internal Revenue relative to the right of a physician to deduct from his income tax expenses incurred in attending medical society meetings. There was also the question as to the right of the Commissioner of Internal

Revenue to search private professional records under the guise of efforts to collect the federal estate tax from the estates of the physician's deceased patients.

THE ADVERTISING COMMITTEE

In order to conduct more formally the decisions on advertising submitted to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION the Board of Trustees had established in the headquarters office an Advertising Committee consisting of Drs. Arthur J. Cramp, Olin West and Morris Fishbein, Professor W. A. Puckner and Mr. C. H. Mohler of the advertising department. Since that time an Advertising Committee of this type has been a regular feature of the conduct of the headquarters office, the purpose being to give scientific consideration to all advertisements that are not directly within the province of the Council on Pharmacy and Chemistry, the Council on Foods and Nutrition, the Council on Physical Medicine and the Council on Medical Education and Hospitals. Indeed the Board of Trustees had authorized the Advertising Committee to reject any advertisements on evidence that a firm was not dealing in complete good faith in its actions toward the medical profession. It was emphasized particularly that all the advertising copy of a manufacturer, as well as the advertisements offered to THE JOURNAL, must meet the standards. In accordance with this action it was recommended also by Dr. Simmons that the publications of the American Medical Association support the councils by refusing to publish manuscripts which promoted the use of nonaccepted products. While this action was not made official, it has guided the decisions of the editorial boards in many instances and thus has saved the medical profession from exploitation by manufacturers who were launching untested and untried remedies on the medical profession.

The Board of Trustees was continually concerned with many matters of minor importance to the general progress but which nevertheless had tremendous interest for the health of the American people. It was attempting to secure improvement in the medical service rendered to Indians under the charge of the Secretary of the Interior. It was working with manufacturers as well as with legislators in an endeavor to prevent distribution of lye and other caustic substances without adequate warning labels. It was endeavoring to secure standardization of thermometers and other apparatus used in the practice of medicine. It was holding continual conferences with Director Frank T. Hines of the Veterans Bureau in an endeavor to limit the training of charlatans under the auspices of the Veterans Bureau and to improve the quality of medical service rendered to the veteran himself.

An assistant editor had been secured for HYGEIA. Attempts were being made to secure suitable field secretaries and assistant secretaries, workers in the field of organizations and for many other functions. At the same time the property of the Association was gradually assuming form. An assembly hall had been added to the plans; new presses and much new equipment were being purchased.

MIDDLESEX MEDICAL COLLEGE

In November 1923 the Middlesex College of Medicine and Surgery notified the Board of Trustees of the American Medical Association that it would not permit the Council on Medical Education and Hospitals to make further inspection of the institution and threatened suit for damages should any reference be made to it in the classification of medical schools published in THE JOURNAL. The Middlesex College of Medicine and Surgery continued to be an irritant in the attempt to secure a high standard of medical education until it finally ceased existence by action of the courts of Massachusetts in 1945.

President Harding died toward the end of the year. President Ray Lyman Wilbur of the American Medical Association had been among the physicians who were in attendance at the time of his passing. The press of the nation had intimated that the death was not wholly due to natural causes. As the years have passed it has become more and more apparent that President Harding died of coronary thrombosis, related no doubt to the strenuous existence that he had followed in a country recuperating with great difficulty from a great war and from mental and other stresses too numerous to mention.

As a result of innumerable conferences with Director Hines of the Veterans Bureau, the American Medical Association had been requested to develop a committee to review ratings for disabilities. This was one of the most important functions rendered by the American Medical Association in the postwar period.

In the meantime the American Medical Association through THE JOURNAL had aided in exposing diploma mills in St. Louis and Connecticut and rackets operated by electic licensing boards in many states. These crusading activities were vastly important in relation to the public attitude toward the American Medical Association.

1924

CHICAGO; DR. SIMMONS RETIRES

When the Executive Committee met early in January in 1924 Dr. Morris Fishbein, assistant to Dr. Simmons, reported a series of interviews with leading editors in New York City as to the prospects for HYGEIA and indicated other measures that had been taken to extend publicity for the American Medical Association in many ways. Articles had been arranged for publication in the *Woman's World;* contact had been made with *Time* magazine, which then had a circulation of 60,000 weekly, relative to the publication of medical news; columns were to be published by the North American Newspaper Alliance, and in other ways publicity for American medicine was to be issued through various channels.

The Bureau of Legal Medicine, through Dr. William C. Woodward, had made contacts with many organizations of the government, and full reports of these were made to the Board of Trustees. They covered such subjects as income taxes, narcotic laws, patents on nostrums, the care of the Indians, animal experimentation, legislation on lye and the standardization of thermometers.

The Board of Trustees was watching carefully the progress of its numerous special periodicals. It recommended expansion of the AMERICAN JOURNAL OF DISEASES OF CHILDREN so that it would contain not only original articles but also abstracts of articles from other periodicals, news and related material.

The Board agreed early in the year that on retirement Dr. Simmons should be known as the emeritus editor of THE JOURNAL.

By this time the functions of the Association in relation to exhibits were assuming increased prominence.

It was being recommended that a Bureau of Exhibits be established with a competent director. Much attention was being given to the formulation of outlines for periodic health examinations. The idea of such examinations was being spread throughout the country by propaganda from many agencies.

Hygeia had reached 18,000 circulation. Many excellent articles were beginning to be selected. Hygeia was being widely quoted in the press and in other periodicals, having an influence far beyond its circulation. Moreover the material in Hygeia was becoming available as reprints and pamphlets, which were extending the circulation to a much more extensive audience.

Then came the epoch making meeting of the Association in Chicago in June.

Professor Puckner, secretary of the Council on Pharmacy and Chemistry, was beginning to feel his advancing years, and Dr. Paul Nicholas Leech was made director of the laboratory.

The Board agreed to anounce to the House of Delegates the resignation of the editor. At this time the Board of Trustees recognized the necessity for taking immediate action for the conduct of the affairs of the Association following the retirement of Dr. Simmons. The names of several applicants were considered. The board eventually agreed that on the retirement of Dr. Simmons Dr. Olin West should become acting general manager, Dr. Morris Fishbein acting editor of The Journal and Mr. Will C. Braun acting business manager, with the understanding that final decisions would be made at a later date.

THE CHICAGO SESSION

The House of Delegates convened for the first time in the Assembly Hall of the American Medical Association building in Chicago. Dr. Frederick C. Warnshuis devoted the first portion of his address to the working methods of the House of Delegates. He recommended that the privileges of the floor of the House be granted to the secretaries of councils and bureau heads for brief reports on their own work, so that the House of Delegates might be more familiar with the men who were carrying on the activities of the Association.

Dr. William Allen Pusey, as President-Elect, discussed particularly the high costs of nurse and medical training and the problem of supplying adequate medical services in rural districts. His address was long and involved essentially a recommendation for abbreviation in the length of the medical and nursing curriculums with the idea of granting the medical degree within four to five years after leaving high school.

The great length of the report of the Board of Trustees made the House of Delegates impatient; it voted to dispense with reading the report and that instead the responsible officials present them an abstract calling attention to the important features. This met with instant approval from the House and has been followed continuously since that time.

SECTARIAN PRACTICE

The Judicial Council had been asked to define "sectarian practice" and to define also the term "physician." These definitions follow:

> A "sectarian," as applied to medicine, is one who in his practice follows a dogma, tenet or principle based on the authority of its promulgator to the exclusion of demonstration and experience.
>
> A physician is one who has acquired a contemporary education in the fundamental and special sciences, comprehended in the general term "medicine" used in its unrestricted sense, and who has received the degree of Doctor of Medicine from a medical school of recognized standing.

Then came a consideration of the relationships of physicians to cultists—a question which has been raised repeatedly and which, it will be remembered, was the fundamental difficulty that arose in New York and caused for a while two medical societies in that state. The report of the Judicial Council on the relationships of physicians and cultists also bears republication:

> Several communications addressed to the Council have raised various questions as to the relationships of physicians with cultists—the attitude that should be assumed by the physician called into a case under treatment by a cult practitioner, whether a pathologist in a hospital under the direction of regular physicians should refuse to examine material submitted by a cultist, and other questions of more or less similar nature. In the opinion of the Judicial Council, these are questions that are not sharply to be defined by words. In his relations with irregular practitioners, the physician should be bound by the Principles of Medical Ethics, chapter II, article I, section 1, while bearing in mind the considerations set forth in sections 6 and 7 of the same chapter and article, and with due consideration for the observations made in the Conclusion on page 23 of the Principles of Medical Ethics of the American Medical Association. In such matters the policy must be governed largely by the circumstances governing the individual case; by the conditions existing in the special community; and by the realization that the first duties of the physician are the care of the sick and, at the same time, the upholding of the dignity and honor of the profession.

At this time also came before the Judicial Council the question of prescribing of eyeglasses with rebates to the ophthalmologist. The Judicial Council referred this to the Section on Ophthalmology for consideration and a request for a recommendation on the subject. Among the most important of the statements made by the Judicial Council also was a supplementary report at this session of the American Medical Association dealing with the vending of the physician's services through an intermediate agency, such as the Public Health Institute in Chicago and the Life Extension Institute, at that time established in New York. So significant was this report that the House of Delegates decided to consider it as a special order of business at a later session.

In its report to the House of Delegates the Council on Medical Education called attention to the diploma mill scandal which had shocked the nation. Several low grade medical schools had sold diplomas and had then shipped their graduates across the country to Connecticut, where the Connecticut eclectic licensing board had arranged for licensure. The situation had been called to public attention by the publication in The Journal of the American Medical Association of the statistics of state board examinations. This had caused the authorities in Connecticut to make an investigation, which resulted in revoking the licenses of 56 physicians and shortly thereafter of another 111, so that 167 physicians in all were declared to have been illegally registered by the eclectic board in that state. Subsequently some of these physicians used their Connecticut licensure to obtain licensure in Arkansas and in Kansas—among them the notorious John R. Brinkley, who at a later date sued the American Medical Association for libel. The Council on Medical Education and Hospitals called attention to the fact that the institutions which were declared to have been involved in the sale of diplomas had long since been in the Council's lowest classification. They were of such low grade that their diplomas were not recognized by the licensing boards of over forty states. Even if those who purchased diplomas had actually matriculated in and attended these medical schools for the required four years and had been regularly graduated, they could not have obtained licenses in more than a few states. That is why the diploma mill ring had to send their "graduates" half way across the continent to get them licensed. Slowly but surely the work of the Council on Medical Education was closing and narrowing the area in which an incompetent physician could attempt to serve the public.

By this time so much interest had developed in anesthesia, radiology and physical medicine that the Council on Scientific Assembly had offered special sessions to these specialties so that they might prove their worth before receiving a section in the American Medical Association.

When a call for new business was made in the House of Delegates, resolutions poured in on the control of cosmetics, on publicity for institutions, on prohibition, on standard methods for reporting deaths in the puerperal state, on the use of zinc stearate dusting powder and on the prescribing of liquor. Again Dr. Franklin Martin addressed the House in behalf of the Gorgas Memorial Institute. At this session the new methods of electing trustees were approved and became a part of the Constitution of the Association. Again the Association appealed for better regulation of the prescribing of liquors.

THE FUTURE OF MEDICAL PRACTICE

Dr. Ray Lyman Wilbur, who had been detained so that he could not make an address at the opening meeting of the House of Delegates, attended the second session and addressed the House on the subject of the future of the medical profession. He pointed out that one of the greatest advantages in the United States is the fact that we have forty-eight states so that any state can try an experiment, and, if it is a bad one, it alone suffers. He recommended more experimentation by the medical profession in methods of preventive medicine and medical care. He said:

> It seems to me, too, that we must keep individualism in medicine if it is to advance, and we must keep individual relations between patients and physicians if medicine as an art is to go forward. The minute we allow a bureaucracy to step in between the physician and the patient, it seems to me we have taken the one step that will degrade our profession and that will put us so that we cannot render ideal professional services to patients.

He felt that too much standardization was injurious to medical advancement. As to service to patients in rural areas, he said:

> Now, to me the rural practitioner problem is not one that we can solve. It is a great social question, this transfer of people from the farms to the cities; it comes with more machinery, with better roads, with gasoline and all that sort of thing, with the changed attitudes of people, with the desire to get more education for the children, and so on. If you will study the population curves, you will see that people are going into the cities from the country, and right now we are having an overproduction on the part of the farms; that to me can be solved only by a million or more farmers moving into the city and going into industry, because we have overproduction on the farms.

In considering the report of the Judicial Council, the House of Delegates adopted the principle that "under no circumstances should a regular physician engage in consultation with a cultist of any description."

As to the practice of medicine by corporations, the House of Delegates, sitting as a committee of the whole, said that the practice should be condemned as against the best interests of the public and that every agency of the Association should do its utmost to educate the people as to the desirability of periodic physical examinations. The Association decided to prepare a special manual to aid physicians in this work.

Dr. William D. Haggard was elected President of the American Medical Association. When the time came for the election of trustees, there was evidence of the manner in which a witticism can swing a legislative body. A distinguished pathologist was nominated for trustee, and a general practitioner was nominated as the opposing candidate. In speaking in behalf of the general practitioner, one of the speakers said "The American Medical Association is not dead, and it does not need a pathologist." There was a tremendous burst of laughter, with an overwhelming vote for the general practitioner.

The House of Delegates at this time referred to the Board of Trustees the ultimate decision on the division of the work of the editor and general manager, and on the concluding day of the session the Board of Trustees announced the action that it had already taken relative to the appointment of Dr. Olin West, Dr. Morris Fishbein and Mr. Will C. Braun.

At the September meeting of the Board Dr. Simmons announced that he was about to leave, and he made a report to the Board of Trustees covering the status of several projects which required action.

The Association was in excellent financial condition. All of its publications were doing well. Dr. Simmons called attention to the fact that the American Medical Association was now in process of developing a package library service, in addition to lending foreign periodicals and furnishing references to literature on various subjects. These services had done much to make available to physicians in remote areas the latest advances in medical science.

SELECTION OF NEW FULL TIME STAFF

At the end of the meeting in September the members of the Board of Trustees appointed a special committee, consisting of Drs. D. Chester Brown, A. R. Mitchell and Charles W. Richardson, to interview candidates for the office of general manager and editor, and the members of the Board were requested to look for available candidates. Dr. Simmons before leaving had prepared an outline of the duties that should be assigned respectively to the general manager, the business manager and the editor.

At this time a considerable disagreement developed between Dr. William Allen Pusey and the Council on Medical Education and Hospitals. Dr. Pusey, as President of the Association, had spoken in behalf of a shortening of the medical curriculum with a view to educating many more physicians and thus supplying the needs of rural areas.

Hygeia had reached an annual circulation of 25,000.

At the November meeting of the Board of Trustees, after much discussion of many of the pending affairs, the Board met in executive session to consider the appointment of a general manager, an editor and a business manager. The minutes merely record that the board met at 8:30 in the evening and that the discussions were long and arduous. After a session which lasted until dawn, the board adjourned. The minutes state only that the subcommittee appointed to procure names of available men from whom a general manager might be selected presented its report. When the Board reconvened in the morning at 9:30 it was moved that Dr. Olin West be elected general manager. This was seconded and carried. The Board then considered the finances of the Association, after which it was moved by Dr. A. R. Mitchell that Dr. Morris Fishbein be appointed editor of The Journal, his duties to be those outlined at the time of his election as acting editor. Then it was moved by Dr. Mitchell that Mr. Will C. Braun be made business manager. These officials were called before the Board and notified of their appointments.

Clinical Notes, Suggestions and New Instruments

CANCER OF THE CERVIX

A Local Recurrence Eighteen Years After Radium Therapy

E. EUGENE COVINGTON, M.D.
Baltimore

I have worked in a tumor clinic for sixteen years, have personally treated several hundred cancers of the cervix in private practice, have had about the average number of local recurrences, almost all of which were within five years, and have seen numerous examples of late metastases; but the following case report of a local recurrence of a squamous cell cancer of the cervix eighteen years after radium therapy is so unusual that I consider it best to record it in the literature. I have never seen a local recurrence this late after any squamous cell cancer, i. e., lip, skin, larynx, pharynx, bladder, tongue or cervix, regardless of whether it was treated by surgical excision or irradiation. Also, I have never seen a new cancer develop in a cervix which had been previously treated by radium.

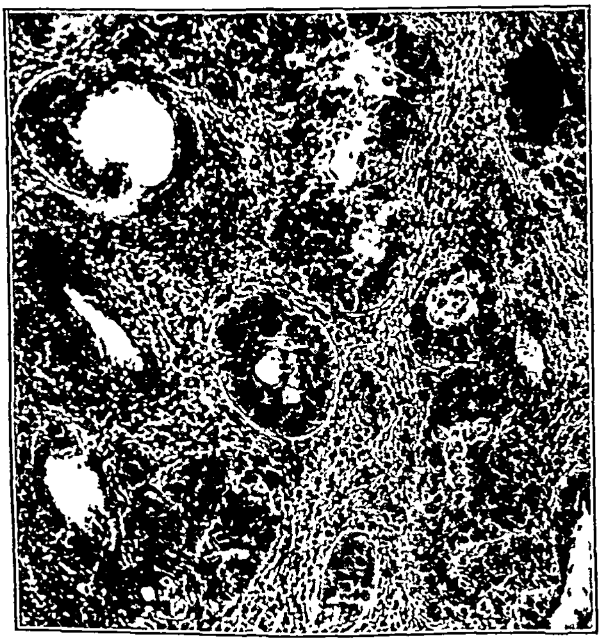

Fig. 1.—Low power photomicrograph of the cancer of the cervix before radium treatment (1929). It is a typical squamous cell cancer with rapidly growing cells and numerous mitotic figures. Note the decided amount of secondary infection.

After a fairly extensive review of the literature on cervical cancer the records of several pathologists and gynecologists of Baltimore hospitals, including the Department of Pathology, University of Maryland School of Medicine,[1] and the extensive surgical pathology records of the late Dr. J. C. Bloodgood[2] were reviewed, and there was no case report of such a late local recurrence and no record of a new cancer developing in a previously irradiated cervix. The opinions of the gynecologists and pathologists varied in this case; most men thought it was a local recurrence of the original growth, but some thought it was a new cancer developing in a previously irradiated cervix.

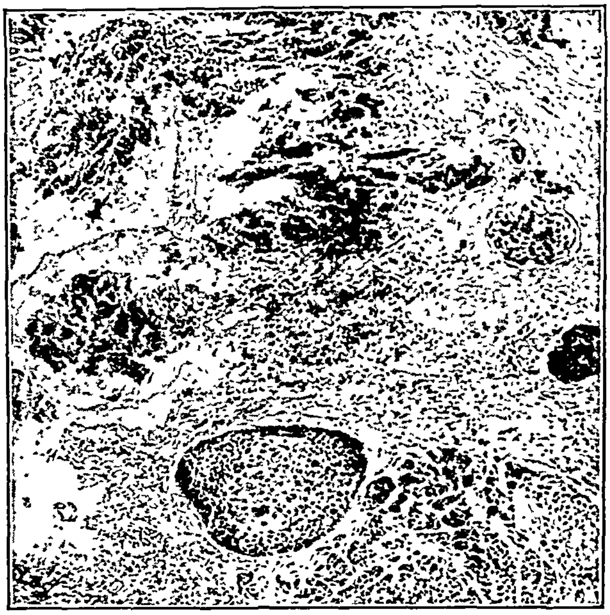

Fig. 2.—Low power photomicrograph of a local recurrence of cancer of the cervix eighteen years after radium therapy. Note the slower growing cancer cells, the absence of infection and the pronounced amount of radiation fibrosis.

REPORT OF A CASE

A white woman aged 41, with a history of two normal pregnancies, entered St. Joseph's Hospital Jan. 25, 1929 with the complaint of vaginal bleeding of six months' duration. Bimanual examination revealed a large, ulcerative type growth of the cervix, filling most of the vault of the vagina. The cervix was almost entirely obliterated by tumor and fixed to the parametrium, but there were no palpable masses in the parametrium. A moderately severe secondary infection was present (fig. 1). The impression, proved by a biopsy (fig. 1), was squamous cell cancer of the cervix, clinically stage 4.

Three applications of radium (Jan. 25, Feb. 10 and Feb. 12, 1929) for a total dose of 5,000 mg. hours of radium were given by Dr. C. R. Edwards, Baltimore. He followed the case for five years, at which time the patient was clinically well and showed no evidence of the growth on vaginal examination.

On Sept. 11, 1946, almost eighteen years after the three radium treatments, the same patient entered St. Joseph's Hospital because of vaginal bleeding and lower abdominal pains of two months' duration. Bimanual examination revealed a growth in the cervix, ulcerative in type and fixed to the adnexa, but no palpable masses were found in the parametrium. A moderate amount of radiation fibrosis of the vagina, parametrium and wall of the rectum with mild stricture formation were also observed on examination. The general condition of the patient was good, and there was no evidence of metastases. The growth was classified clinically as stage 3 cancer of the cervix. A biopsy showed squamous cell cancer (fig. 2).

The treatment was as follows: 2,000 r of 400 kilovolt roentgen therapy over each of four pelvic areas (two anterior and two posterior) was given over a period of four weeks, using

---

From the Department of Radiology, St. Joseph's Hospital.

[2] Quoted by permission of Drs. George A. Stewart and L. C. Cohn, associates of the late Dr. J. C. Bloodgood.

a heavy Thoreus filter and 50 cm. distance. This was followed immediately by an application of intrauterine and contracervical radium (3,600 mg. hours of radium).

At the present time (two months after treatment) the general condition of the patient is good, the local growth has entirely disappeared, there is no evidence of metastases and the bleeding and discharge have stopped; the patient's only complaint is mild diarrhea and rectal pain from irradiation proctitis and a slight stricture of the rectum.

SUMMARY

A local recurrence of a squamous cell cancer of the cervix eighteen years after radium therapy is reported and, as far as I can determine from the literature, this case represents the longest interval of time on record before such a local recurrence of a squamous cell cancer of the cervix.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

ABSTRACT OF MINUTES OF MEETING OF THE COUNCIL ON PHYSICAL MEDICINE, DEC. 13 AND 14, 1946

The Council on Physical Medicine held its regular annual meeting on Friday and Saturday, Dec. 13 and 14, 1946. Those present were Drs. Morris A. Bowie, Eben J. Carey, Anthony C. Cipollaro, W. W. Coblentz, John S. Coulter, A. U. Desjardins, W. E. Garrey, Frank H. Krusen, Frank R. Ober, George M. Piersol and H. B. Williams.

Dr. John S. Coulter was reappointed chairman and Dr. Frank H. Krusen, vice chairman. On Thursday, December 12, preceding the meeting of the Council, a joint meeting was held with the Council on Industrial Health, the Consultants on Roentgen Rays and Radium and the Consultants on Atomic Energy. Those present were Drs. William E. Chamberlain, Arthur C. Christie, Edwin C. Ernst, Gioacchino Failla, Hymer L. Friedell, Raymond Hussey, Anthony J. Lanza, Robert R. Newell, Eugene Pendergrass, Carl M. Peterson, Ursus V. Portmann, Stanley J. Seeger, J. L. Weatherwax and Harold O. Wyckoff.

Reviewing the work of this joint meeting, the Council on Physical Medicine decided that the problems under consideration were of particular interest to the Council on Industrial Health and to both groups of consultants and concluded that it would be extremely difficult to separate the two fields. The plan of merging the work of the two groups of consultants into one with a common name was discussed but abandoned. The Council finally decided, in view of the general interest of the profession in radioactive isotopes and atomic energy, that a special group of consultants be retained. The Secretary was advised to present all matters dealing in the field of roentgen rays and radium and radioactive isotopes to both consultant groups.

Dr. Robert R. Newell was appointed a member and chairman of the Consulants on the Medical Aspects of Atomic Energy. Dr. A. U. Desjardins, member of the Council, was appointed chairman of the Consultants on Roentgen Rays and Radium.

The Council confirmed the action of the consultants (1) to appoint a subcommittee to study problems arising in the fields of radon and thorium-X; (2) to appoint a subcommittee on nomenclature for selecting terms used specifically in roentgen rays, radium and radioactive isotopes and to cooperate with the American Standards Association and with other national bodies dealing with fundamental definitions; (3) to gather all available information regarding isotopes and prepare an article for publication in The Journal; (4) to prepare a statement on the danger of radiant energy; (5) to study methods of guarding against injury to employees in industrial plants where radioactive isotopes are manufactured, and (6) to advise physicians on the dangers associated with the use of radioactive isotopes as tracers in diagnostic procedure.

Dr. George M. Piersol reported on the progress made in the investigation of clinical thermometers. The Council appointed a group of specialists to advise him in the survey.

The problems relative to ultraviolet radiation for disinfecting purposes were discussed. The Council voted to reaffirm its stand—that is, to accept ultraviolet lamps only for use in operating rooms, baby cubicles and nurseries in hospitals. Furthermore, the Council voted that advertising for disinfecting lamps be not accepted or the lamps retained on the accepted list if they are recommended for installation in school rooms, theaters, manufacturing establishments, business offices, refrigerators, sterilizers and poultry and animal husbandry establishments.

In the opinion of the Council, critical evidence is not available at the present time to substantiate the claims made but the members of the Council pointed out that careful consideration will be given to any new evidence that comes to light.

The Council voted to reaffirm its adopted report "Therapeutic Value of Ultraviolet Radiation," in which the therapeutic indications and contraindications of ultraviolet radiation are considered and voted to reaffirm its adopted report "Medical Diathermy." The "Tentative Minimum Requirements for Acceptance of Diathermy Apparatus" were revised, and the Council voted to authorize its Secretary to refer the requirements to the manufacturers for comment and criticism before being published.

The Council discussed its work in the fields of occupational therapy, education, ophthalmology and audiometers and hearing aids.

The members were informed that the Board of Trustees had voted to refer the activities of the Committee on American Health Resorts to the Council on Physical Medicine. The inspection of health resorts will be done in the future as in the past by the Council on Medical Education and Hospitals.

An exhibit at the one hundredth annual session of the American Medical Association in June was proposed. This exhibit will be separate from the special exhibit on physical medicine supported by the Board of Trustees. The Council was gratified to learn that a session on physical medicine has been established by the House of Delegates. At least one afternoon at the next annual session will be devoted to the problems of physical medicine.

For many years the Council has steadfastly refused to recognize the term "iron lung" as a synonym for respirator. Popular usage of the term "iron lung" to describe a certain type of respirator is very well established. The Council recognizes that general acceptance of a word by the press establishes its meaning. Since the Council was of the opinion that "iron lung" was not a strict scientific description of the apparatus in question, the term was not permitted in acceptable advertising. The Council voted to retain the name "respirator" to describe the device.

For two years the Council has sponsored research in artificial respiration. A report was given by Drs. Andrew C. Ivy and Henry Schwerma on the research which has been conducted under their supervision. Results of these surveys will be published in due time. The Consultants on Ophthalmic Devices have been active in advising the Council relative to the use of instruments in the practice of ophthalmology. Dr. Thomas D. Allen presented a report for the Consultants and stated that articles for publication on contact lenses and artificial eyes will be prepared and submitted to the Council for adoption. The Council was gratified to learn that articles on orthoptics had been favorably received by members of the profession interested in these problems.

The work of the Consultants on Audiometers and Hearing Aids was reviewed by Dr. W. E. Grove. This group has rendered valuable service to the Council and to the cause of scientific medicine.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association.

James R. Wilson, M.D., *Secretary.*

PREPARATIONS USED IN THE FEEDING OF INFANTS (*See* Accepted Foods, 1939, p. 156)

Libby, McNeill and Libby, Chicago, Ill.

Libby's Strained and Homogenized Vegetables with Lamb, Milk and Barley.

Analysis (submitted by manufacturer).—Total solids 15.50%, moisture 84.50%, ash 1.04%, fat (ether extract) 2.81%, protein (N × 6.25) 3.66%, crude fiber 0.43%, carbohydrates other than crude fiber (by difference) 7.56%.

Calories.—0.70 per gram; 19.88 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	1,085 U. S. P. units
Thiamine	0.026 mg.
Riboflavin	0.082 mg.
Ascorbic acid	1.10 mg.
Niacin	0.64 mg.
Calcium	40.80 mg.
Phosphorus	65.10 mg.
Iron	0.88 mg.
Salt	620.00 mg.

Libby, McNeill and Libby, Chicago, Ill.

Libby's Strained and Homogenized Pears and Pineapple.

Analysis (submitted by manufacturer).—Total solids 16.35%, moisture 83.65%, ash 0.35%, fat (ether extract) 0.07%, protein (N × 6.25) 0.36 %, crude fiber 0.87%, carbohydrates other than crude fiber (by difference) 14.70%.

Calories.—0.61 per gram; 17.32 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	5 U. S. P. units
Thiamine	0.031 mg.
Riboflavin	0.017 mg.
Ascorbic acid	1.40 mg.
Niacin	0.20 mg.
Calcium	11.20 mg.
Phosphorus	12.90 mg.
Iron	0.84 mg.
Salt	30.00 mg.

The Beech-Nut Packing Company, Canajoharie, N. Y.

Beech-Nut Junior Squash.

Analysis (submitted by manufacturer).—Total solids 10.3%, moisture 89.7%, ash 0.5%, fat (ether extract) 0.3%, protein (N × 6.25) 1.1%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 8.3%. Specific gravity 1.053.

Calories.—0.4 per gram; 11 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	2,540 U. S. P. units
Thiamine	0.018 mg.
Ascorbic acid	2.90 mg.
Riboflavin	0.063 mg.
Niacin	0.19 mg.
Calcium	30.00 mg.
Phosphorus	12.00 mg.
Iron total	0.90 mg.
Iron "available" (bipyridyl method)	0.70 mg.
Copper (McFarlane method)	0.20 mg.

The Beech-Nut Packing Company, Canajoharie, N. Y.

Beech-Nut Strained Vegetables with Bacon.

Analysis (submitted by manufacturer).—Total solids 18.25%, moisture 81.75%, ash 1.47%, fat (ether extract) 4.12%, protein (N × 6.25) 1.72%, crude fiber 0.29%, carbohydrates other than crude fiber (by difference) 10.65%.

Calories.—0.87 per gram; 25 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	1,220 U. S. P. units
Thiamine	0.047 mg.
Ascorbic acid	0.42 mg.
Riboflavin	0.056 mg.
Niacin	0.67 mg.
Calcium	27.00 mg.
Phosphorus	38.00 mg.
Iron total	0.28 mg.
Iron "available" (bipyridyl method)	0.19 mg.
Copper	0.17 mg.

The Beech-Nut Packing Company, Canajoharie, N. Y.

Beech-Nut Junior Vegetables with Bacon.

Analysis (submitted by manufacturer).—Total solids 16.78%, moisture 83.22%, ash 1.61%, fat (ether extract) 3.54%, protein (N × 6.25) 1.53%, crude fiber 0.25%, carbohydrates other than crude fiber (by difference) 9.85%.

Calories.—0.77 per gram; 22 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	1,033 U. S. P. units
Thiamine	0.035 mg.
Ascorbic acid	0.79 mg.
Riboflavin	0.040 mg.
Niacin	0.84 mg.
Calcium	28.00 mg.
Phosphorus	30.00 mg.
Iron total	0.43 mg.
Iron "available" (bipyridyl method)	0.28 mg.
Copper	0.15 mg.

The Gerber Products Company, Fremont, Mich.

Gerber's Ready to Serve Barley Cereal.

Analysis (submitted by manufacturer). — Total moisture (indirect method) 7.2%, total ash 4.4%, fats (acid hydrolysis) 4.9%, protein (N × 6.25) 13.2%, crude fiber 1.1%, carbohydrates other than crude fiber (by difference) 69.2%.

Calories.—3.7 per gram; 106 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Thiamine	2.69 mg.
Riboflavin	0.84 mg.
Calcium	494.0 mg.
Phosphorus	680.0 mg.
Iron	51.0 mg.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

MENADIONE (See New and Nonofficial Remedies, 1946, p. 650).

The following dosage forms have been accepted:

E. S. Miller Laboratories, Inc., Los Angeles

Solution Menadione (in Oil), 1 mg. per cc.: 1 cc. ampuls. Each cubic centimeter contains 1 mg. of menadione with benzocaine 2 per cent. Preserved with 0.5 per cent cresol.

Tablets Menadione: 1 mg.

The Vale Chemical Co., Inc., Allentown, Pa.

Tablets Menadione: 2 mg.

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1946, p. 395).

The following dosage form has been accepted:

Barlow-Maney Laboratories, Inc., Cedar Rapids, Iowa

Tablets Aminophylline: 0.1 Gm. and 0.2 Gm.

Premo Pharmaceutical Laboratories, Inc., New York

Enerels Aminophylline: 0.1 Gm. Each tablet is enteric coated with a shellac-castor oil mixture.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1946, p. 251).

The following dosage form has been accepted:

Abbott Laboratories, North Chicago, Ill.

Bismuth Subsalicylate in Oil with Chlorobutanol 3%: 1 cc. ampuls; 30 cc. and 60 cc. bottles. A suspension of bismuth subsalicylate in a mixture of peanut oil and ethyl esters of olive oil fatty acids containing in each cubic centimeter 0.13 Gm. of bismuth subsalicylate and chlorobutanol 3 per cent with metaphen 1:20,000.

ASCORBIC ACID (See New and Nonofficial Remedies, 1946, p. 631).

The following dosage form has been accepted:

Buffington's Inc., Worcester, Mass.

Tablets Ascorbic Acid: 25 mg., 50 mg. and 100 mg.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street - - Chicago 10, Ill.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MARCH 29, 1947

"HISTORY OF AMERICAN MEDICAL ASSOCIATION"

The instalment of the "History of the American Medical Association" which appears in this issue of The Journal covers the years 1920-1924. With this instalment publication of the history will be discontinued in The Journal. The complete history of the Association up to June 1947 will appear in the volume which is to be published by the W. B. Saunders Company for the American Medical Association. There will be additional chapters on "The Home of the American Medical Association," "Dr. George H. Simmons," "The Libel Suits of the American Medical Association" and "The Indictment and Trial of the American Medical Association by the U. S. Government." The second part of the book will include biographies of the one hundred presidents of the American Medical Association with a picture of each and with facsimile signatures of all but one. These have been prepared by Dr. Walter L. Bierring. The third part of the book will be devoted to the Councils and Bureaus of the American Medical Association, except for some of the Councils whose work is fully described in the general account of the Association's work. The articles on the work of the Councils and Bureaus have been prepared in most instances by the secretaries of these agencies, with the exception of the article on the Judicial Council, which is written by Dr. Morris Fishbein. The history of the Advertising Department has been prepared by Mr. Thomas R. Gardiner, business manager. The fourth part of the book concerns the publications of the American Medical Association other than The Journal and includes articles descriptive of the history of each of them. In most instances these articles were prepared by the present chief editor of the periodical concerned. An appendix will provide tabular data, including places of meeting, the membership of many of the Councils and similar subjects. The book will be completed with both a name and a subject index. The publishers anticipate that the book will be available for distribution at the Centenary in Atlantic City in June.

PROGRESS IN OTOSCLEROSIS

A recent report on twenty years of research in otosclerosis and related problems[1] presents some interesting observations on the prevention and treatment. Davenport, Milles and Frank, who studied the distribution of clinical otosclerosis in several generations of sixty families, found that the females in these families were affected about twice as frequently as the males. When both parents were deaf, nearly all their daughters and nearly two thirds of their sons were deaf. However, the studies of Davenport indicate that the type of blood does not indicate who would be expected to develop defects conducive to otosclerosis. The observations of Guild support the contention of other workers that when the deafness was caused by otosclerosis it was due solely to an ankylosis of the stapes. His statistical studies suggest that in the United States there are between ten million and twelve million white people with otosclerosis and that 1,000,000 to 1,200,000 of these have ankylosis sufficient to cause deafness.

Fowler stresses the importance of a prior audiogram in the early diagnosis of otosclerosis. For this children should be tested on first entering school and again before entering high school. The most encouraging information revealed by research, according to Fowler, is the evidence that otosclerosis need not necessarily progress to deafness in each instance but may become arrested at any stage of its development. There is, however, no cure for the lesions of otosclerosis. Even when it is prevented or arrested there will be no change in inheritability under favorable environmental conditions.

Preventive treatment consists in careful supervision in otosclerotic families of the mother during pregnancy and the puerperium. Such general measures as attention to diet, ample vitamin and mineral contents and correction of any detected abnormality may in some measure offset the tendency in the mother and the infant toward the condition. Loss of hearing from otosclerosis may be lessened by prostheses such as hearing aids of the air or bone conducting variety. A number of these have been accepted by the Council on Physical Medicine of the American Medical Association and are quite efficacious.

The most promising operative procedure is fenestration with its many modifications. Fenestration, in the opinion of most otologists, will restore serviceable hearing in a large percentage of properly selected patients. The principal causes of operative failure result either from closure of the new window by formation of new bone or by development of fibrous tissue, or from secondary postoperative labyrinthitis. A number of modifications, such as the insertion of a movable cartilage stopple or of a perforated stopple, hold promise of still better results.

---

[1] A Report of Progress: Twenty Years Research in Otosclerosis, Progressive Deafness and Correlated Problems, 1926-1946.

The report mentions anatomic studies on the developmental changes and their possible correlation with the mechanics of the ear carried on at Wisconsin and Northwestern universities. At Columbia University Fowler attempted without success to produce otosclerosis from deficient diets in rats. These experiments, supported in whole or in part by the Central Bureau of Research of the American Otological Society, Inc., have contributed much toward greater knowledge of the physiologic and pathologic processes involved in otosclerosis.

IMPROVED MUMPS VACCINE

Mumps as a disease of military personnel may be exceedingly troublesome, causing loss of time from duty and interfering with the movement of troops. Extensive investigations were therefore undertaken by Enders and his associates[1] of Harvard Medical School in hope of developing specific diagnostic methods for doubtful cases and the discovery of a successful prophylactic vaccine.

In their initial experiments about 3 cc. of saliva collected on the first and second days of the disease in a typical human attack was introduced into the Stensen duct of a monkey (Macacus mulatta). On the fifth day the gland, which was somewhat enlarged, was removed, emulsified and inoculated into both ducts of a second monkey. On the seventh day the second animal presented swelling of both parotid glands with subcutaneous edema of both cheeks. In this way the virus was passed through a series of monkeys, some of which received bacteriologically sterile material obtained by filtering the parotid emulsion through an Elford collodion membrane.

Antigens for use in complement fixation tests were prepared from weighed portions of the infected glands removed at the height of the experimental disease. They found that the serums of monkeys taken before inoculation or at the height of the experimental infection do not fix complement in the presence of this antigen. Serums from monkeys during convalescence invariably fix complement in titers varying from 1 : 128 to 1 : 2,048. Complement fixing antibodies persist in convalescent serum for at least three and a half months. Similar results were obtained from human beings.

This antigen may have numerous practical applications. Extensive applications, however, will presumably depend on the discovery of a more readily available and cheaper source of antigen than extracts from infected monkey glands. In an attempt to find such a cheaper and more abundant source of vaccine, the Harvard investigators[2] succeeded in cultivating the virus in the developing hen's egg. They were unable to cultivate it in the embryonated yolk sac, but serial transfers were readily effected in the amniotic fluid and amniotic membranes of the developing embryo. In many cases as little as a 1 : 1,000,000 dilution of the amniotic fluid produced infection in monkeys.

The virus is modified during its growth in the amniotic fluid and acquires power to agglutinate hen's erythrocytes. This property is not shown by the initial monkey gland virus. This acquired power of hemagglutination is inhibited by the serums of human beings and monkeys convalescent from mumps.

The earlier attempts to prepare a prophylactic mumps vaccine were made with formaldehyde treated virus from the parotids of infected monkeys. Injection of this nonviable formaldehyde treated vaccine into the parotids of normal monkeys did not produce local swellings of the glands, but did give rise to the development of complement fixing antibodies in the animals' blood. Maximum titer was reached by the eighteenth to thirtieth day. About 60 per cent of these vaccinated animals developed a slight but distinct resistance to subsequent infection with viable mumps virus. In certain instances, however, evidence of increased resistance to experimental inoculation was not demonstrable, yet complement fixing antibodies were found. Clinical tests[3] showed that the same slight but ineffective immunity can be produced by repeated subcutaneous injection of the formaldehyde treated virus in human beings.

More encouraging results were obtained in subsequent tests[4] with a viable mumps vaccine. This vaccine was attenuated by prolonged serial cultivation in the embryonated hen's egg. After twenty-five serial passages in the egg, the virus introduced directly into the parotid gland of the monkey no longer gives rise to the typical experimental disease. From six to fourteen weeks later, however, the vaccinated animals exhibited a solid resistance to experimental inoculation with virulent material.

These experiments have led to the expectation that the new improved mumps vaccine will prove to be a successful prophylactic agent in man, comparable to the viable vaccines employed against smallpox and yellow fever. Clinical tests of the new viable vaccine are now in progress.

Current Comment

EFFECT OF VACCINATION ON INCIDENCE OF INFLUENZA B

Hirst and his colleagues[1] have studied the value of influenza vaccination in an epidemic of influenza B. They compared a group of 550 men attending Yale University as part of their Army Special Training Program who had received mixed A and B influenza vaccine with a group of 1,050 unvaccinated naval students studying at the same institution under similar circumstances. In the early part of November 1945 an epidemic of influenza caused almost entirely by the B virus developed. The number of cases reached a peak in about four weeks and was rapidly subsiding by the middle of December. Three cases of influenza appeared in the vaccinated group and 132 cases in the unvaccinated group, giving attack rates of 0.5 and 12.5 per cent respectively. The investigators believe it highly probable that the difference in attack rate could be attributed to the vaccination of the army group with influenza virus treated with formaldehyde. This report presents additional evidence of the value of vaccination against influenza and suggests that it may be more effective against influenza B than against influenza A.

A PURIFIED EQUINE ENCEPHALOMYELITIS VACCINE

Equine encephalomyelitis of the virus type has occurred in horses and mules in all but three of the forty-eight states. The disease is transmissible to man. According to Randall and his colleagues,[1] sanitary measures designed to reduce contact with insect vectors of the disease can be of some effect, but most satisfactory protection for animals and under certain circumstances for human beings is given by active immunization. Previously prepared vaccines of this type have proved satisfactory for administration to horses, but their high content of chick tissue and egg components have made them potentially dangerous for human beings. Randall and his group consequently tried to develop a concentrated virus preparation suitable for use by human beings. Three types were prepared, eastern, western and Venezuelan, by a two stage differential centrifugation process. The purified vaccines were characterized by a content of chick and egg proteins definitely lower than that of the crude vaccine used for the immunization of horses and mules and of commercial human type vaccine. All three types of vaccine confer active immunity to guinea pigs against the homologous type of virus even when the virus is injected directly into the brain. Furthermore, antibodies neutralizing the eastern type virus were demonstrated in the serums of guinea pigs following the administration of eastern type vaccines and in the serums of human subjects following the injection of a mixture of eastern and western types of vaccine.

RECURRENT CEREBRAL THROMBOSIS AS A NOSOLOGIC ENTITY

There are still obscure diseases about which much can be learned by direct observation of their symptoms and course. The clinical description of disease—nosography—emphasized by Hippocrates and reemphasized by such observers as Sydenham, Allbutt and Osler is by no means completed. In a recent contribution Alvarez,[1] under the heading "cerebral arteriosclerosis with small, commonly unrecognized apoplexies" describes the clinical manifestations of this condition as observed and interpreted by him. As yet the disease thus presented is not generally understood. The condition is not described in the books and of course has no independent status in official statistics. The reason the condition is not better known appears to be mainly that cases have not been observed closely over the years of its long course followed by necropsy and thorough study of the brain at the end. According to Alvarez the cases, which may extend over many years and examples of which he reports in detail, are characterized by episodes attributed by him to thrombotic injuries to the brain and by more or less profound changes in the health, character, ability and habits of the patient. On account of its length the whole story can usually be obtained only from relatives or old friends. The first episode can come in the forties or even in the thirties. Often the illness dates from a peculiar attack at a certain time, the first one in a series of more or less typical minor "strokes." Alvarez summarizes the chronic symptoms and diagnosis in part as follows: "Diagnosis is fairly easy when the patient suddenly changes in character and ability. Some never work again. Many have an unexplained nervous breakdown. Some become somewhat psychopathic and a difficult problem in the home. Some deteriorate morally. . . . Many lose their grooming and go about with dirty clothing. . . . Acute episodes are often thought to be attacks of 'acute indigestion.' . . . Often in order to make the diagnosis one must talk to the relatives and business associates. They alone will tell of sudden aging and of big changes in character and ability." Alvarez ascribes the symptoms to thrombosis of small arteries in the brain, with necrosis of brain tissue. Silent areas of the brain may be affected as well as centers and tracts. He takes it as granted that the fundamental process is sclerosis of small cerebral arteries, but as yet a thorough study has not been made of the brain in typical cases with complete clinical records. He himself refers to only one necropsy and pictures scattered thrombotic foci in the brain. He points out the need of close correlation of the clinical phenomena with the results of morphologic studies of the cerebral lesions. Opportunities which frequently will come to the pathologist to work so to speak backward should not be neglected. When the brain is found speckled with little brown spots and scars in a case without any record of the symptoms, questioning of the family and friends may yield significant information. Active cooperation by clinician and pathologist is required to advance the understanding of recurrent cerebral thrombosis.

ORGANIZATION SECTION

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Report of Meeting in Chicago, Jan. 11, 1947

The Joint Committee for the Coordination of Medical Activities met at the American Medical Association Building in Chicago, Saturday, Jan. 11, 1947. Those present included:

Col. George E. Armstrong
Dr. Walter L. Bierring
Dr. Warren F. Draper
Capt. William E. Eaton
Dr. Morris Fishbein
Dr. E. L. Henderson
Mr. Thomas A. Hendricks
Mr. J. W. Holloway Jr.
Dr. Ernest E. Irons
Dr. B. R. Kirklin
Dr. George F. Lull
Dr. James M. Mason
Col. Hugo Mella
Dr. F. V. Meriwether
Dr. J. J. Moore
Dr. H. B. Mulholland
Dr. James E. Paullin
Dr. Carl M. Peterson
Lieut. Col. William N. Piper
Father A. M. Schwitalla, S. J.
Dr. R. L. Sensenich
Dr. Dean F. Smiley
Miss Mary Switzer
Lieut. Col. John H. Voegtly
Mrs. M. V. Shuler

COMMITTEE REPORT TO SUPPLEMENTAL SESSION OF THE HOUSE OF DELEGATES

The Chairman gave a résumé of the report he had prepared and presented before the Supplemental Session of the House of Delegates of the American Medical Association in December and read the report of the Reference Committee commending the continued activity of the committee under its new name (The Journal, Dec. 28, 1946, pp. 1077 and 1092).

CHANGES IN MEMBERSHIP

The Chairman made the following announcements concerning changes in membership: Mr. Barry C. Smith, a member of the American Medical Association Committee, is unable to continue membership for reasons of health and has suggested that the Commonwealth Fund might continue to be represented by Dr. Lester J. Evans, medical associate; the Surgeon General of the United States Public Health Service has appointed Dr. Palmer Dearing, chief of the Division of Commissioned Officers, to represent the Public Health Service, succeeding Dr. Warren F. Draper, and has asked Dr. F. V. Meriwether of Chicago to attend the January 11 meeting since Dr. Dearing cannot attend; the American Red Cross, on request, has indicated its desire to join the deliberations of this committee, which enables the Committee to have the continued membership of Dr. Draper as the Red Cross representative; Dr. H. B. Mulholland of Charlottesville, Va., a member of the Committee on Rural Medical Service, will represent that committee in place of Dr. F. S. Crockett, resigned.

The Committee accepted Mr. Smith's resignation with regret and welcomed the suggestion that Dr. Evans succeed him, representing the Commonwealth Fund.

QUESTIONNAIRE OF COMMITTEE ON RURAL MEDICAL SERVICE

The Chairman presented copies of a questionnaire that had been sent out by the Bureau of Information under the name of the Committee on Rural Medical Service and the Joint Committee for the Coordination of Medical Activities and stated that while the Joint Committee at its meeting in October had discussed the desirability of obtaining information as to the present physician population, especially with respect to the probable postwar changes in distribution, no action involving a questionnaire had been taken. The Committee approved the questionnaire bearing the name of the Joint Committee.

Dr. Mulholland said that the purpose of the questionnaire is primarily to gather information on the distribution of physicians throughout the country at the present time and that it is hoped to have some data compiled for presentation in an exhibit at the Atlantic City session of the American Medical Association in June. Miss Switzer suggested that in assembling data provided through the questionnaire use might be made of the latest distribution reports the Procurement and Assignment Service had when it was dissolved, so that changes in the situation since that time could be shown. She thought that such a comparison would reveal the change in the distribution as influenced by relocating returned medical officers. Dr. Paullin said that most of the states have the Procurement and Assignment data in readily accessible form.

The Chairman added that it would be expected that reports on the results obtained would be provided for the information of the Joint Committee. Mrs. Shuler of the Bureau of Information informed the Committee that the questionnaire had been sent, with a covering letter, to the secretaries of the state medical societies, who are distributing them with a letter of explanation to the county medical societies.

REPORT OF SUBCOMMITTEE ON SURPLUS MEDICAL, DENTAL AND HOSPITAL SUPPLIES

Father Schwitalla, Chairman of the Subcommittee, said he had nothing further to report but would like to suggest to the Joint Committee that one last effort the Subcommittee might make before being discharged is to attempt to secure the reactivation of Directive 23, issued some time last summer by the War Assets Corporation, which was to have expired—he thought—on Dec. 31, 1946. This directive made available to educational institutions surplus supplies of rather large and important character. The reactivation of Directive 23 so that its provisions would carry over into 1947 or for an indefinite time might be of advantage.

Miss Switzer, a member of the Subcommittee, stated that she had been going to recommend that the Subcommittee be discharged, but in view of Father Schwitalla's suggestion perhaps this one thing could be done and the Subcommittee continue in existence at least until the next meeting. She further said that the manner of distribution of surplus supplies in the medical field has been and is extremely confused, but there does not seem to be anything that any one can do about it now except that perhaps this one directive could be reactivated and much accomplished; the War Assets Corporation is trying to do a good job, but the pressure to dispose of these supplies commercially is almost irresistible.

The Committee voted to ask Miss Switzer to urge the reactivation of Directive 23. The Committee was reminded that the War Assets Corporation is legally required to distribute surplus property to educational and health institutions under certain conditions, at, however, the Corporation's discretion.

There was discussion of the position in which individuals are placed in the matter of securing surplus property, and it was the consensus that the situation is deplorable, Dr. Paullin stating that many of the returned medical officers are unable to open offices because they cannot get equipment of any kind from any source.

The Chairman stated that the Subcommittee would be continued until the next meeting in order that an attempt may be made to secure the reactivation of Directive 23.

SPECIALTY BOARD FOR GENERAL PRACTITIONERS

Dr. Bierring, Chairman, read a report of the Subcommittee on Specialty Board for General Practitioners, appointed at the October 12 meeting. The other members of the Subcommittee are Dr. Kirklin and Dr. Sensenich.

The subcommittee is submitting this report as a preliminary one, because the many problems involved make further study necessary before a final report and proper recommendations can be formulated.

Recently there has been a decided revival of interest and activity by and for the general practitioner in some form of certification or special designation for those physicians who are engaged in the general practice of medicine. With the growth of specialization in medicine and the certification of the different medical specialties, it is becoming increasingly difficult—as well as an unfortunate necessity—to draw a sharp line between general practice and the different forms of limited or specialized practice.

The general practitioner has, or believes he has, some very definite complaints against the overweaning influence of the specialist. Some of these are inadequate proportional representation in the government of medical societies and medical affairs generally; lack of opportunity for postgraduate study in comparison with that afforded specialists; lack of recognition among physicians generally of the professional attainments of the general practitioner, and the fact that, the general hospital in no way recognizes the general practitioner as such in its staff organization.

The overwhelming influence of the specialist in medical affairs denies the general practitioner a reasonable opportunity to keep abreast of modern progress by the tendency to relegate all institutional medical work to specialists of one kind or another, which is, at present, the procedure adopted by the Veterans Administration in the appointment of attending and consulting staffs. Patients complain that it is difficult even to find a general practitioner, and this is traceable in part to the present organization of hospital staffs, which does not provide a place for a general practitioner.

What procedure should be considered for the more dignified recognition of general practice to make it the keystone of medical service? Several methods of experimentation have been proposed, and some are being carried out.

Thus far it has been difficult to define general practice adequately or to define the function and place of the general practitioner in the present scheme of medical practice. In a general way it is thought to include a general comprehensive diagnostic and therapeutic knowledge of general medical and surgical disease conditions, ability to make a complete health examination, qualification for the treatment of general uncomplicated disorders of children or of the skin, and qualification for the practice of obstetrics and minor surgery—the cultured family doctor and adviser.

What should be the character of certifying or qualifying tests for the general practice of medicine? At the Congress on Medical Education and Licensure in February 1941 the late Dr. Louis B. Wilson, director of the Mayo Foundation and member of the National Board of Medical Examiners, in reviewing the results of twenty-five years of the board's activities, suggested that its examination, which was and is today the most comprehensive test, written and practical, of knowledge for the general practice of medicine now operating in this country, might serve as a pattern or means of certifying or specially qualifying physicians for general practice. It was further suggested that diplomates of the National Board remaining in general practice for five or ten years and giving evidence of having progressed by further study be elected as fellows of the National Board. A special committee was appointed to study the practicability of the suggestion, but the advent of World War II discontinued this activity. At the present time it is unlikely that the National Board can undertake the certification for general practice on a national basis because of the magnitude of the task. However, in any plan for the certification of physicians for general practice, the National Board examination might well serve as a pattern and its certificate considered for reciprocal recognition.

One state medical association, Indiana, has developed a definite plan for the certification of general practitioners. This plan is now in operation. The by-laws of the Indiana Board of General Practice of Medicine, Inc., provide, among other things, that:

"The original membership of this organization shall be composed of not more than two hundred reputable physicians engaged in the general practice of medicine, who have been so engaged for at least ten years.

"Additional members shall be general practitioners of medicine who have passed the examination provided for in these by-laws and presented to the board of directors satisfactory proof of the following qualifications:

"1. Membership in a local county medical society and citizenship of the United States.

"2. High moral and ethical standing in the profession.

"3. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

"4. Completion of an approved internship, preferably of the general rotating type, in a hospital approved by the same Council of the American Medical Association.

"5. Continuance of postgraduate education.

"6. A minimum of five years of general practice after completion of an approved internship.

"In special instances the board may accept for examination outstanding candidates who were in practice prior to Jan. 1, 1930 but whose formal training does not comply with the full preliminary requirements stated herein.

"The examination in which all applicants shall be required to make a passing grade shall include:

"Part I. A review of case reports.

"Part II. A written clinical examination.

"Part III. An oral clinical test.

"Part IV. Demonstration of ability at bedside and in laboratory.

"The following is an outline of matters to be included in each of these four parts:

"Part I. The candidate must file twenty-five case reports, in condensed form, for which he was personally responsible. These case reports must be sufficiently complete to enable the examiners to evaluate the judgment of the candidate in his choice of procedure and must include

"1. An account of the candidate's personal observation of the case.

"2. The basis for diagnosis.

"3. The facts which determined the course of treatment.

"4. Critical conclusions to be drawn from the outcome of the case.

"These case reports may cover a variety of material in one or more of the following fields: infectious diseases; deficiency diseases; diseases of metabolism; neoplastic diseases; diseases of the gastrointestinal tract, respiratory system, kidneys, blood-forming organs, circulatory system, glands of internal secretion, nervous system, bones, joints and muscles; obstetrics; pediatrics; dermatology; neuropsychiatry; office gynecology; surgery, and allergy.

"Part II. The written examination will cover the basic medical sciences, and subjects pertaining to the general practice of medicine, having in view the determination of the question as to whether the applicant possesses the quality and extent of medical knowledge necessary for general practice of a high order.

"Part III. The oral clinical test will be directed to the ascertainment of the candidate's familiarity with recent medical literature, the breadth of his clinical experience, his capabilities, general adaptability, comprehension and understanding of the patient's problems as a whole, and other qualifications requisite for highly competent general practice.

"Part IV. Demonstration of ability at bedside and in laboratory will include the assignment of one or more patients in a hospital to the applicant so that his approach and procedure in handling a new patient may be observed by the Committee on Examinations.

"Applicants who successfully complete one part of the examination may proceed to the next part in the order in which the parts are listed until they have completed the entire examination. Whenever an applicant fails to pass the examination, or any part of it, the Committee on Examinations, on request, will make suggestions as to suitable courses of instruction or other means of improvement through which the applicant may overcome any deficiencies causing such failure. Any applicant who fails to pass an examination, may, on payment of an additional fee of $15, take another examination." (The first fee accompanying the application is $25.).

The by-laws further provide that there shall be a president, a vice president, secretary and treasurer of the corporation, who shall be members of the board of directors, and that the board of directors shall consist of fifteen members. There also is provision in the by-laws for the revocation of a certificate, causes for revocation being given as "violation of the Principles of Medical Ethics of the American Medical Association, misrepresentation or fraud in obtaining a certificate, conduct unbecoming to a physician or discrediting to the board," also "if the license to practice medicine of any physician holding membership in this corporation is revoked or suspended, or if he is expelled from his county medical society, such event shall operate as a revocation of his certificate . . ." Hearings in cases of proposed revocations are provided for in the by-laws and "a vote of at least two thirds of the members or directors present at the hearing" is required to revoke.

It is understood that other medical societies are considering similar plans.

This subcommittee desires at this time to make the following recommendations:

1. That general hospitals be encouraged to establish a special service for general practice.

2. That special residencies in general practice be established wherever practical.

3. That in the development of certifying specialty boards for general practice on a state level (*a*) reasonable consideration be given to the older general practitioners being placed in the founders group; (*b*) additional examinations be required or evidence be submitted at least every ten years of progressive practice or postgraduate studies; (*c*) postgraduate courses, institutes or seminars be developed for diplomates of general practice or prospective applicants for the certifying examination and the interest of specialists in such courses enlisted; (*d*) some form of general supervision or unification of procedure of certification, a central coordinating influence, be established on a national basis, and (*e*) every possible source of publicity and education in regard to this new movement be encouraged.

The subcommittee thoroughly appreciates the importance of this whole matter with respect to the future practice of medicine in this country, and it therefore urges further careful study by the American Medical Association and other professional agencies concerned.

Miss Switzer thought it would be extremely important to have a national board for general practitioners and asked for enlightenment as to what would happen to physicians who are qualified doctors of medicine and general practitioners, and who might not be interested or eligible for membership in a board such as described, and also if the Joint Committee thinks the establishment of such a board would close the gaps in the present specialty certification so that any doctor who is worth anything would, one way or another, be connected with a specialty board.

Dr. Sensenich said that this matter has been a source of concern to a great many physicians. The success of any project depends on how well the field is covered, and when a substantial portion of any mechanism is excluded the project is doomed to failure. Basically, the specialty boards were set up originally to improve the standards of specialization and, basically also, in the interest of the patient. As a result they have become more or less an aristocracy from which the general practitioner is excluded, and the general practitioner feels this to be so. Thus, a hard and fast line is drawn between the specialists and the remaining sixty or seventy thousand physicians who are general practitioners. If you are going to select from that group a relatively small number for special recognition and certification, you create from the residue a vast group who will not be in sympathy with the program. It would seem desirable to include in the remaining program every doctor who wants to practice good medicine. Perhaps there should be a national board to conduct examinations such as are conducted by the National Board of Medical Examiners; perhaps such a special board could create some term that would designate the individual general practitioner who, from year to year, makes an effort to continue his practice on a high plane; in other words, some pattern might be devised for continuing graduate work from year to year that would be available to all. The essential thing is that the general practitioner must have access to the hospitals, where he will do his work under supervision and do it much better than outside with no supervision.

Dr. Kirklin made the comment that this is an extremely important subject among physicians at the moment. At a recent meeting of the house of delegates of a state medical association four resolutions pertaining to the general practitioner were introduced, one of them calling for the establishment of a certifying board and the other three condemning the specialty boards as being to blame for the alleged exclusion of the general practitioner from hospital staffs. Most hospitals now are demanding that surgery done in the hospital be done only by those who are certified; this excludes the general practitioner who can and wants to do hospital surgery. In some states hospitals have gone so far as not to allow any one to take care of patients in the hospitals unless he is certified by a specialty board. That is an action by the hospitals themselves and not of the boards. One of the resolutions just mentioned recommended that hospitals establish sections on general practice to enable the general practitioner to take his patients into the hospital. It is possible that in the effort to raise the standards of medical practice too drastic steps may be taken. The Indiana movement resulting in the establishment of the Indiana Board of General Practice already has spread; Ohio is now contemplating the creation of a board of general practice.

The Chairman made the following statement concerning the origin and development of the various specialty boards: The specialty boards were set up originally for the protection of the public; before there were any boards any one could set himself up as a specialist merely by saying he was one, and often men who were calling themselves specialists were not particularly well prepared in the specialties they professed. Another factor in the organization of the specialty boards was that the founders saw in them an opportunity for stimulating continuing education of the younger men and a means for further elevating the quality of medical practice. The effect of the organization of these boards has been tremendously greater than any one had any conception of when the movement began. The founders group of the American Board of Internal Medicine, for instance, set up its plans of operation with the expectation of examining probably 200 applicants a year; at the examinations in 1946 there were 800 applicants; however, that is probably a larger number than will be examined in future years since it included many men who had been in the armed services and had not had opportunity to take the examination. During the war, when cooperation could be obtained from the commanding officer, the written part of the examination was conducted overseas. The Surgeon Generals of the Army and Navy gave the most cordial cooperation. This activity contributed to the war effort in no small degree. Fifty per cent of the interns are calling for residencies in specialties because they want to qualify for certification by a specialty board. Whether they qualify or not, they will have spent five years of additional study and the natural corollary is that the public will be provided with better treatment. Thus, from an educational point of view and from the point of view of the betterment of the public health, the specialty boards have accomplished enormously more than was expected. As to the other side of the picture, very early in the movement the administrators of some state welfare laws insisted that only certified practitioners in certain specialties would be eligible for appointment to newly created positions. Other physicians felt that there was, thus, improper discrimination against them. A great many hospitals wanted to be approved by the Council on Medical Education and Hospitals and so thought they should require that every staff member be certified. Many capable physicians in hospitals have never become certified in any specialty. Then, the Army and Navy gave preference in Army and Navy hospitals to those certified. In these ways the movement has grown. It does not help the general practitioner. It would not appear to be wise, however, for the Advisory Board for Medical Specialties to have a part or responsibility, even an advisory responsibility, in the overall certification of general practitioners, since it is difficult to see how that could be done and the board's standards for its other work maintained. The quality of medical education, medical procedure and medical practice in this country has risen enormously in the past twenty years. The Army and Navy found that out during the recent conflict. Nothing should be done that would tend to interfere with the progress of the improvement of medical practice. There is much to be said for the idea that there ought to be a very liberal interpretation of what constitutes a good practitioner, but if you skim off a layer of cream you still have a large residue. It is no fault whatever of the specialty boards that hospitals are demanding that all men on their staffs be certified.

Father Schwitalla said that the hospitals are the victims in this movement; it is the hospital staffs that have taken the lead in the new regulations, and the hospital administrations have followed that lead.

Dr. Henderson agreed with Father Schwitalla, saying that the hospital administration has often followed the staff, and the members of the various boards have controlled the staff, which, in turn, controls the administration; much of this has come about because of the shortage of hospital beds.

It was Father Schwitalla's opinion that the increasing number of certifications has made the matter crucial, that the problem is very much smaller where the staff has taken a broad attitude, and that where there is freely given consultation there is no major problem and the general practitioner is perfectly willing to come in, especially in the obstetric department. He said the general practitioner should be encouraged to call for consultation. He also said that in the course of the past four or five months he had interviewed many graduates of St. Louis University School of Medicine and had learned that a greater number than formerly are planning to go into general practice.

Dr. Sensenich suggested that out of the residue of physicians who are not acceptable to the specialty boards some of the group might be permitted to take examinations for certification, but beyond that point some designation might be given to individuals without examination who display evidence of doing good work, continuing their education and trying to keep up to date; this pattern might be formed on a national basis.

Dr. Kirklin stated that most of the specialty boards will not admit a physician to examination unless he furnishes a statement that at least 75 per cent of his practice is limited to his specialty, and some of the boards require 100 per cent. The subject was further discussed by Dr. Mason, Father Schwitalla, Dr. Bierring and Miss Switzer.

TAFT-FULBRIGHT BILL (S. 140)

The Chairman brought to the attention of the Committee a report which appeared in the morning newspapers (Saturday, January 11) that Senators Taft and Fulbright had introduced a bill in the Senate for the establishment of a Department of Health, Education and Security, which calls for a secretary of cabinet rank, with three under secretaries for health, education and security.

After lengthy discussion the Chairman stated that a résumé of the various remarks would be prepared for the minutes, and the Committee voted for the appointment of a subcommittee to study the subject and be prepared with essential facts for discussion at the next meeting of the Joint Committee. The Chairman appointed as members of the new subcommittee Dr. Walter L. Bierring, chairman; Dr. R. L. Sensenich, and Miss Mary Switzer.

A résumé of the discussion on the Taft-Fulbright Bill follows:

Dr. Fishbein. A conference called by the National Social Welfare Assembly and the American Council on Education is to be held in Washington on *January 31. Representatives of a great many organizations* have been asked to attend and discuss the Taft-Fulbright measure. It would be well for those who are to speak for the medical profession to have some understanding of the basic considerations: The desirability of having a secretary in the President's Cabinet to cover the three branches involved or of having a division in the government which would be quite independent of security, the problem of guarding and guiding the selection of the cabinet officer, and, finally, the type of activity that should be included. Obviously, health has many aspects closely related to education and security. The American Medical Association has been asked to send two representatives to the conference, but its sponsors have not asked for a representative of medical education, and the bill includes funds for medical education. The first meeting is for preliminary discussion, and there probably will be three or four meetings before they get to the point of making recommendations. If the fact that there is no representative of medical education in the conference should be brought before the group, the leaders in education and security would welcome liaison near the top.

The Joint Committee for Coordination of Medical Activities should talk about this bill and make recommendations for consideration to its parent bodies.

Miss Switzer. It would be an advantage to have a Cabinet officer. Opportunities for communication and discussion regularly established with the President do not exist when an agency has no Cabinet member at its head. If the head of the department were a member of the Cabinet, he might be able to put across the point of view his agency advances. Right now it would be impossible to get three Cabinet posts, one for health, one for education and one for security, but one post covering all three might be obtained.

Father Schwitalla. The recognition of professional aspects under each one of these three heads is just as important as, even more important than, the single Cabinet member. I would like to see the strongest possible statement about safeguarding professional aspects in each one of the three fields. The provision of medical care has to be safeguarded. Recognition of professional interests and the specific requirements of each of the three departments as well as the interrelationships of the departments should be written into the law.

Dr. Sensenich: The profession would definitely oppose appointment of a man whose experience has been entirely in overseeing a health agency.

Dr. Fishbein. I am sure the education people would have the same attitude in their field, as to the security field, any one probably would be acceptable.

Dr. Draper. The man who is under secretary for health should have exactly the same organization and should be the same kind of man who would be the secretary in the Cabinet.

Father Schwitalla: The difference between the top man and the under secretary would not lie in any other thing except in the professional qualifications.

Miss Switzer. It would be wise to try to safeguard the points mentioned and leave out the rigidity of the assignment of bureaus; try to get the mandates for the secretary written in very general terms, avoiding a rigid internal organization.

Father Schwitalla. The National Education Association is going to have a lot to say where college and professional education enter into the picture.

Dr. Fishbein: The present Commissioner of Education always has had a liberal attitude and recognizes that the control of education is distinctly a local matter. Suppose the next man, as head of a federal bureau, conceives it his duty to say "We set the pattern of teaching"? It can be seen that there are distinct hazards in control by indirect means in a bureaucracy.

Miss Switzer. If the wrong type of professional person is in one of these important places, the public interest is very apt to be entirely ignored. The political agencies of government should have, in a broad *sense, a broad public interest. It is important to keep a balance between* the necessities and the proper professional qualifications and at the same time not to overlook the fact that the officials do represent the public interest.

Father Schwitalla: There should be in the bill a full recognition of the work of the private agencies in all three fields according to the pattern of the Hill-Burton bill where the words "private agencies" are incorporated in the crucial parts.

Miss Switzer. That is right. There ought also to be something in the bill about advisory *councils and committees* and some sort of continuing counsel for the administrator.

HOSPITAL RESIDENCIES

In the absence of Dr. Victor Johnson, the Chairman read the following statement:

Since the last meeting of this committee there have been no great changes in the status of hospital residencies and physician veterans. The number of requests for appointments is diminishing, although approval of new institutions for such training is continuing.

SUPPLY OF MEDICAL STUDENTS

The Chairman read the following report from Dr. Johnson:

The Council on Medical Education and Hospitals is now compiling enrolment statistics for the freshman class that entered medical schools in the autumn of *1946.* We have received the figures to date from fifty eight medical schools. In these schools there is a total enrolment of 4,268. This figure may be compared with the enrolment in last year's freshman class, which in the schools thus far reported amounted to 4,291. This indicates that the decrease in enrolment in the fifty eight schools is not very great. Enrolments have been maintained because of the large number of veterans admitted. In the schools reported, these totaled 2,491, which constitutes about 58.4 per cent of freshmen in these fifty eight schools. The figures for nineteen institutions have not yet been received.

Father Schwitalla commented that with reference to the future of medicine there may be some misinterpretation of the contrasting figures presented by Dr. Johnson. He stated that a spot study made in the colleges of arts and sciences about two months ago revealed that the student mortality—defections—at the end of the '45-'46 school year was so much less that some of the colleges are a great deal worried as to what is to be done with the upper classmen. The number of failures has dropped from 20 per cent to 9 per cent, so that the sophomore, junior and senior classes will be very much larger and, if that should be the case in the medical schools, there will be a distinct problem. He thought some of the reasons for the better showing on the part of college students are that the present students are older, more earnest and want to be educated and there probably is a little better selection among students admitted to college because of the great number trying to get in.

Dr. Johnson's report was accepted as one of progress with the anticipation that he would have something more to report at the next meeting.

GRADUATE EDUCATION AND LOCATIONS FOR PRACTICE OF PHYSICIAN VETERANS

The Chairman presented letters from physician veterans serving residencies under the G. I. bill, in which complaints were made that the Veterans Administration is not allowing them the money to which they are entitled under the G. I. bill for the purchase of books.

Father Schwitalla stated that the Veterans Employment Service and its branch offices throughout the country are receiving requests concerning locations for practice from a continuingly large number of veteran physicians and dentists and that the Employment Service would like to be as helpful as possible. He asked if the Joint Committee for the Coordination of Medical Activities might not properly request the American Medical Association and the American Dental Association to give out statements which could be used by the Veterans Employment Service in all its branches telling them where to refer physicians and dentists for the desired information. He thought that perhaps the men now being demobilized have not had the benefit of the counseling that was given formerly, and Miss Switzer also thought that the men who were at demobilization points for counseling purposes a year ago are no longer there. Dr. Lull said the American Medical Association would be very glad to send a statement such as suggested by Father Schwitalla.

Dr. Lull commented that the man who has come out of service finds himself involved in a vicious circle; he took his state board examination when he got out of school; he is now a resident in a hospital and cannot become a member of a county medical society while he is a resident and cannot take a specialty board examination because he is not a member.

Father Schwitalla, chairman of the Subcommittee on Graduate Education of Physician Veterans, said: An ordinary civilian's patience becomes exhausted eventually, and it is a question whether one should keep on pushing a federal agency or let the federal agency have its way. When we first tried to organize the graduate instruction of residents there was a definite plan. Then we were told that the cost had to be justified, and now there has to be a cost sheet showing the expenditures. Unfortunately, the recognized medical schools and hospitals are coming into the same category as some "fly-by-night" schools, and there is no means of control.

Colonel Mella commented that in the last published minutes of the Joint Committee there was quite a critical review of the residency program under the G. I. bill and that the Veterans Administration already has had a repercussion in that some think the criticism applies to the administration's own institutions. He thought that some statement should come from the Joint Committee that the criticism does not apply to the Veterans Administration hospitals.

It was agreed that the criticism applies to the residency program under the G. I. bill being carried on in civilian hospitals, and Dr. Fishbein said that a definite statement to that effect could be prepared for an early issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Father Schwitalla said that when in March 1946 the V-12 and ASTP programs were discontinued a regulation was published that all students in schools of medicine who had been in those programs and had not had at least ninety days of active service were not eligible for educational benefits under the G. I. bill, but that a month or so later the regulation was withdrawn, and it was stated that those ASTP students would be eligible even without having served in military units. The reason for the change was that men started under those auspices were stranded in the midst of their educational programs. In order to be sure that a person would not just say he was going to medical school and then not go, the boys had to sign a waiver that they would continue their education as civilians. Within the last month or so a regulation has been published withdrawing the previous regulation, and these boys are stranded again. The motivation for the second withdrawal was that the boys had signed a statement that they would continue as civilian medical students, and therefore the government is exonerated from responsibility. Father Schwitalla wondered whether these boys should be left on their own or whether an attempt should be made to do something for them. He estimated that from 35 to 40 per cent of the V-12 and ASTP students are involved.

Dr. Fishbein said that many factors are involved and that there are several sides to the picture; that those boys who were in the V-12 and ASTP programs were a favored group who did not contribute to the military service and many who were in the programs wanted to get out immediately on cessation of hostilities. He also said that the government is supporting half the students and not the other half, and it would seem that the process should stop somewhere.

There was further discussion by Dr. Lull, Father Schwitalla, Dr. Paullin, Colonel Piper and Dr. Fishbein, and the consensus seemed to be that there is little or nothing which can be done by nongovernment agencies.

AMERICAN RED CROSS BLOOD BANK PROGRAM

Dr. Fishbein presented for the information of the Committee a résumé of a nationwide blood bank and donor program being worked out by the Red Cross. This will be reported on more fully at a later meeting.

SURVEY OF MEDICAL SCHOOLS

For the information of the Committee, the Chairman read the following statement prepared by Dr. Johnson:

> On recommendation of the Council on Medical Education and Hospitals, the Board of Trustees of the American Medical Association has authorized a complete survey of all the medical schools of this country. Although the American Medical Association will undertake the entire financial responsibility for the survey, such a project can achieve the end of improved medical education in this country only as a collaborative effort with the Association of American Medical Colleges and the individual colleges. The aim of the survey will be that motivating every activity of the Council in the past: to improve medical education and to render all assistance to medical schools to improve themselves so that the quality of medical care in this country will continue to improve and the position of world leadership in medical education occupied by the schools of this country will be maintained and strengthened.

REPORT OF SUBCOMMITTEE ON ESTABLISHMENT OF MEDICAL CORPS IN VETERANS ADMINISTRATION

Father Schwitalla, chairman, said that the subcommittee had nothing new to report, but Colonel Mella requested that the subcommittee be continued so that if new problems should arise in the Veterans Administration's setup the subcommittee might be of assistance in solving them.

Discussion followed of the position of osteopaths in the Veterans Administration, participated in by Dr. Bierring, Colonel Mella, the Chairman, Miss Switzer and Dr. Draper.

RURAL MEDICAL SERVICE

The Chairman presented Dr. H. B. Mulholland, a member of the Committee on Rural Medical Service, who has taken the place on the Joint Committee of Dr. F. S. Crockett as a representative of the Committee on Rural Medical Service. Dr. Mulholland spoke as follows:

> The main efforts of the Committee on Rural Medical Service at the moment are directed toward the second annual National Conference on Rural Health, which is to be held in Chicago on February 7 and 8. It is expected that the conference will be well attended, more than 250 persons already having indicated their intention to be present.
>
> Virginia is now undertaking an investigation with reference to prepayment medical insurance for rural people. The rural people not only want the prosperous farmer covered but also the indigent.
>
> The Committee on Rural Medical Service is also concerned with the Hill-Burton Hospital Construction Act and its extension to rural people, and regional and state chairmen have been asked to contact the proper people in each state to see that rural people are on the committees in each state.
>
> Cooperatives have recently become numerous in the West. These groups are interested in medical care and the extension of medical care to rural areas. The Committee on Rural Medical Service feels that an attempt should be made to work out some plan with the cooperative groups for adequate rural medical care.

Dr. Mulholland's report was accepted with appreciation, and he was asked to present further information at the next meeting.

HEALTH AND PHYSICAL FITNESS PROJECT

Dr. Smiley gave the following report on the activity in the Physical Fitness Project now being conducted by the American Medical Association under the guidance of himself and Mr. Fred V. Hein:

> The Joint Committee on Health Problems in Education requested us to prepare material on three subjects: (*a*) Health Appraisal of the School Child, (*b*) Facts About Common Health Problems and (*c*) Cooperation in School Health Work. This material has been prepared and is now in the hands of the Joint Committee to be used in its work.
>
> Work in the field has included attendance on a rural life conference and a meeting of the State Physical Education Association in Arizona and a health education conference in Wisconsin; a survey of the Kenosha, Wis., public schools, and attendance on three teachers' institutes and one nurses' institute in Cook County, Ill.
>
> We have given assistance to Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation, in his study of the proposed National School Health Services Act, initiated and sponsored by *Parents' Magazine*. Mr. George J. Hecht of *Parents' Magazine* is chairman of a national committee working for the enactment of the act. This bill, if enacted, will provide assistance to the several states to enable them to establish and develop school health services for the prevention, diagnosis and treatment of physical and mental defects of school children.
>
> A conference on the cooperation of the physician in the school health and physical education program is being planned to be held Oct. 16 and 17, 1947.
>
> We are working closely with Dr. Harold R. Hennessey of the Council on Industrial Health, preparing health education material for the benefit of the C. I. O. - U. A. W. Institute of Health.
>
> Investigation is being made of the possibility of providing technical advice to the 35 mm. entertainment film producers who are planning a series of health shorts.

Miss Switzer said that the school health services bill has been under consideration for many months and, while it still is far from perfect, it represents a step forward in cooperative effort and areas of agreement. Dr. Bierring thought there is great expansive implication in the bill. He said that it assumes complete health care of school children up to 16 years of age, implies an infringement on the interests of at least 60,000 practitioners and places authority in the educational agencies of the state, and that the bill should receive very careful consideration and scrutiny. Miss Switzer thought that the latest plan was that it would be jointly operated by the health and education authorities and that the coordination would be effected by the head of the Federal Security Agency.

NAVY MEDICAL CORPS

Captain Eaton read excerpts from letters written by Reserve Corps medical officers complaining of not being allowed to resign and also that they are "not entitled to medical care." He stated that the remarks are not true, that of 618 resignations submitted only 218 are still pending, and that it is the intention to accept all resignations by the end of the fiscal year. He went on to say that a law had been passed which encouraged Naval Reserve officers to transfer to the regular service but that pressure is not being put on any one to do so and, if they do transfer, they go into the regular service without an examination of any kind and at the rank held in the Reserve but eventually they may be given or revert to a lower grade. Captain Eaton stated also that Navy, Army, Marine Corps, Public Health Service, Coast Guard or Veterans Administration personnel are admitted to navy hospitals and the Navy is required to give medical care to dependents. He said there is a total census of 3,802 medical officers in the Navy, which is insufficient to man all the stations adequately, especially in the hospitals.

MODEL HOSPITAL LICENSING LAW

Father Schwitalla told the Committee of a model hospital licensing law for the states, the first draft of which had been prepared by the American Hospital Association, which is being promoted by the Council of State Governments. He said the legislation is primarily a result of the enactment of the federal Hill-Burton Hospital Construction Act, which, while it does not specifically require the enactment of a state hospital licensing law, does require that a participating state must by July 1, 1948 enact legislation requiring that the maintenance and operation of hospital facilities financed in part by federal funds shall meet prescribed standards.

Dr. Sensenich remarked that the purpose or intent of the bill is highly desirable but thought that the matter of licensing an institution is a very important step and that perhaps there should be a conference of some kind covering the medical aspects of the bill. Dr. Lull said that the Director of the Bureau of Legal Medicine and Legislation and the Secretary of the Council on Medical Education and Hospitals of the American Medical Association have had the model bill under scrutiny. Father Schwitalla stated that the American Hospital Association is very active in its promotion.

PROFESSIONAL TRAINING IN THE ARMY MEDICAL CORPS

Col. George E. Armstrong of the Army Medical Corps, visiting a meeting of the Joint Committee for the first time, was introduced and spoke as follows:

> A professional training program for Army Medical Corps personnel was begun as of Jan. 1, 1947 and 175 men have been assigned to residencies in eight permanent army general hospitals. For the purpose of making these residencies acceptable to the various specialty boards, 250 certified specialists are acting as consultants.
>
> The regular Army Medical Corps is still depleted. As of today, Jan. 11, 1947, there are 1,131 officers in the regular establishment—less than before the war. Only 158 officers were integrated during 1946. The authorized strength, depending on legislation, will be between 2,150 and 2,750. A bill is being prepared which will provide means for more rapid promotion, revitalization of the Medical Corps by more strict attention to ways of getting rid of "dead wood," increased pay for specialists who are certified by specialty boards and some other things that it is thought will make the service more attractive. The bill is now in the process of being finally approved by the legislative section of the War Department, after which it is hoped to correlate it with the Navy.
>
> To date 47,100 physicians have been separated from the Army Medical Corps. About forty Medical Corps men are now in civilian hospitals or medical schools taking training, the largest number, perhaps, training in public health.

TIME AND PLACE OF NEXT MEETING

It was voted to hold the next meeting at American Medical Association Headquarters in Chicago at 10 a. m., Feb. 22, 1947.

The meeting adjourned at 1:25 p. m.

GENERAL REGULATIONS PROMULGATED UNDER FEDERAL HOSPITAL SURVEY AND CONSTRUCTION ACT

A Condensation Prepared by the Bureau of Legal Medicine and Legislation

As required by section 622 of the Federal Hospital Survey and Construction Act, general regulations have recently been promulgated by the Surgeon General of the United States Public Health Service with the approval of the Federal Hospital Council and the Administrator of the Federal Security Agency. They relate, in general, to (*a*) the number and distribution of general hospital beds required to provide adequate hospital service, (*b*) the number and distribution of beds required to provide adequate hospital services for tuberculous, mental and chronic disease patients, (*c*) the number and distribution of public health centers, (*d*) the general manner for determining priorities, (*e*) the general standards of construction and equipment of hospitals, (*f*) the availability of hospital facilities without discrimination on account of race, creed or color and (*g*) the general methods of administration of state plans.

Definitions.—Section 10.1 of the new regulations defines the term "hospital" to include public health centers and general, tuberculosis, mental, chronic disease and other types of hospitals and related facilities, such as laboratories, outpatient departments, nurses' home and training facilities, and central service facilities operated in connection with hospitals, but not institutions furnishing primarily domiciliary care. Except as applied generally to public health centers, the term "hospital" will be restricted to institutions providing community service for inpatient medical or surgical care of the sick or injured and obstetric care. The term will exclude federal hospitals and institutions found to constitute a public hazard.

A "public health center" is defined to mean a public facility utilized by a local health unit for the provision of public health services, including related facilities such as laboratories, clinics and administrative offices operated in connection with public health centers.

This section also indicates that "public health services" means services provided through organized community effort in an endeavor to prevent disease, prolong life and maintain a high degree of physical and mental efficiency. In addition to the services which the community already provides as a matter of practice, the term will include such additional services as the community from time to time may deem advisable to provide.

Other definitions contained in this section include, among others, the terms "base area," "intermediate area," "rural area," "general hospital," "chronic disease hospital," "mental hospital," "nonprofit hospital," "tuberculosis hospital," "hospital bed" and "local health unit."

Distribution of General Hospital Beds.—Sections 10.11 to 10.14 inclusive deal with the distribution of general hospital beds. The number of such beds required to provide adequate hospital service to the people residing in the state is declared to be (*a*) 4.5 beds per thousand of population in states having 12 or more persons per square mile, (*b*) 5 beds per thousand of population in states having less than 12 and more than 6 persons per square mile and (*c*) 5.5 beds per thousand in states having 6 persons or less per square mile.

The construction program under a state plan must provide for general hospital beds, existing and proposed, in each area within the state in accordance with the following standards: (*a*) in states having 12 or more persons per square mile, 2.5 beds per thousand of population in rural areas, 4.0 beds per thousand in intermediate areas and 4.5 beds per thousand in base areas; (*b*) in states having less than 12 but more than 6 persons per square mile, 3 beds per thousand of population in rural areas, 4.5 beds per thousand in intermediate areas and 5 beds per thousand in base areas, and (*c*) in states having 6 or less persons per square mile 3.5 beds per thousand of population in rural areas, 5.0 beds per thousand in intermediate areas and 5.5 beds per thousand in base areas.

Distribution of Tuberculosis, Mental and Chronic Disease Hospital Beds.—The number of beds required to provide adequate hospital services for tuberculous patients, mental patients and chronic disease patients in any state is declared to be, (*a*) for tuberculous patients, 2.5 times the average annual deaths from tuberculosis in the state over the period of five years from 1940 to 1944 inclusive, (*b*) for mental patients 5 per thousand of population and (*c*) for chronic disease patients 2 per thousand of population.

Wherever practicable, tuberculosis, mental and chronic disease hospitals will be built in centers of population and in proximity to general hospitals.

Distribution of Public Health Centers.—The number of public health centers in a state, counting those existing as well as those provided with federal aid under the Survey and Construction Act, may not exceed 1 per 30,000 of state population except that in states having less than 12 persons per square mile the number may not exceed 1 per 20,000. In the count of public health centers, however, the following will be excluded: (*a*) existing facilities which the state agency, after consultation with the state health authority, has determined to be unsuitable for use as public health centers and (*b*) auxiliary facilities such as laboratories and clinics, whether existing or proposed, and whether they are located within the same structure as the health department office or in a separate structure.

The general method of distribution of public health centers throughout the state must conform to the plan of organization of local health units within the state.

Priority of Projects.—Sections 10.41 to 10.47 inclusive indicate the general rules to be observed in establishing priorities. With respect to public health centers, highest priority must be given to the provision of facilities for local health units serving the rural commmunities and areas with relatively small financial resources.

General Standards of Construction and Equipment.—Appended to the regulations is appendix A, which sets forth the general standards of construction and equipment that have been developed by the Surgeon General of the United States Public Health Service. The regulations require the state agency to adopt general standards of construction and equipment for the various types of hospitals and health centers assisted under the program and that such standards shall not be less than the general standards set forth in appendix A. The minimum standards that have been set up for public health centers are as follows:

(B-8). Public Health Centers.

Administration.—Where health department administration personnel has no offices in health center: waiting room, public toilets, office for public health nurses, staff toilets. Assembly space: waiting room may be used for this purpose where health centers serve under 30,000 population. Where health department administration offices are provided in health centers, add health officer's office, office for sanitary engineers, health education office, staff room and library in health center for over 30,000 population.

Clinical.—The clinical services, and extent of such services, provided in the health center will depend on the program contemplated by the health department to take care adequately of the particular needs of the population served by the health center. For populations up to 30,000, two examination rooms for maternal and child health, venereal disease and tuberculosis clinics, consultation room, utility room and dental room. For populations over 30,000, if the following services are provided, they shall include areas noted as follows: Maternal and child health: demonstration room, examining room, toilet. Tuberculosis and X-Ray: X-ray room with dressing booths, dark room, consultation and viewing room. Venereal disease: examination room, treatment room, consultation room, toilet. Dental: two dental chairs, small dental laboratory. Pharmacy: Dispensing room.

Laboratory.—The volume and type of laboratory tests in the health center will vary with local conditions and will determine the size of the laboratory. Such factors as density of population, area to be served, type of center (municipal, county or rural), its use as a branch of the state laboratory and availability of other laboratory facilities must be considered. One room is required for urinalysis, hematology and dark field examinations for syphilis and storage of biologic products furnished by the state health department. Where food control, sanitation and communicable disease work is contemplated, another room shall be furnished for this purpose.

Service.—General storage areas: bulk office and janitors' supplies, bulk clinical supplies, educational material. Storage closets: office supplies, medical supplies, educational material. Janitors' closet: centrally located. Heating plant.

The regulations provide that application for construction of a psychopathic hospital with a capacity of more than 500 beds or of a mental hospital with a capacity of more than 3,000 beds shall not be approved. Similarly, application for construction of a tuberculosis hospital with a capacity of less than 100 beds will not be approved, except that an application for construction of a tuberculosis hospital with a capacity of 50 to 100 beds may be approved when necessary to provide facilities for an isolated area too small to support a larger hospital.

Nondiscrimination and Hospital Services for Persons Unable to Pay Therefor.—A state plan must provide for adequate hospital facilities for the people residing in a state without discrimination on account of race, creed or color and must provide for adequate hospital facilities for persons unable to pay therefor. Before a construction application may be recommended by a state agency for approval, assurance must be obtained from the applicant that the facilities to be built will be made available without such discrimination. In any area, however, where separate hospital facilities are provided for separate population groups, the state agency may waive this requirement if (*a*) it finds that the plan otherwise makes equitable provision on the basis of need for facilities and services of like quality for each such population group in the area and (*b*) such finding is subsequently approved by the Surgeon General.

Similar assurance must be received by the state agency that the applicant will furnish a reasonable volume of free patient care, defined to mean hospital service offered below cost or free to "persons unable to pay therefor," both the legally indigent and persons who are otherwise self supporting but are unable to pay the full cost of the hospital care.

Methods of Administration of a State Plan.—The concluding sections of the regulations indicate the manner in which state hospital construction programs are to be developed and how construction applications are to be processed.

Washington Letter

(From a Special Correspondent)

March 28, 1947.

Senator Taft Asks Billion Dollar Budget for Social Welfare

Senator Taft, Republican of Ohio, told the Senate Banking Committee that "it is no more socialistic to provide government assistance to furnish housing than it is to give free medical care, as they do in every general hospital." Senator Taft testified on the long term housing bill he introduced with Democratic Senators Wagner of New York and Ellender of Louisiana. He asserted that the government could afford to spend $1,000,000,000 annually for social welfare programs in health, housing and education. Mr. Taft said he would like to see the federal budget cut to $28,000,000,000 in fiscal 1949 and to $25,000,000,000 in fiscal 1950. He said the $1,000,000,000 social welfare budget would not be too large with a reduced overall federal budget.

House Approves Permanent Army and Navy Nurse Corps

The House of Representatives has passed legislation to establish permanent nurse corps for the Army and Navy. The bill sponsored by Representative Smith, Republican of Maine, was passed without objection after an anti-race discrimination amendment offered by Representative Powell, Democrat of New York, was defeated by a standing vote of 187 to 47. Mr. Smith said that the amendment by Powell, one of two Negro House members, was unnecessary because the Navy no longer discriminated against Negroes and now has Negro nurses.

Reports of Alarming Spread of Tuberculosis in Europe

Dr. Arnold P. Meiklejohn, senior nutrition consultant in the United Nations Relief and Rehabilitation Administration's European office, told a Washington news conference that an alarming increase in tuberculosis has made it Europe's most severe infectious disease. He estimated the overall death rate from tuberculosis now to be at least twice the prewar level and in some places much higher. There is widespread underfeeding in Europe and an increase in infant mortality. UNRRA, he said, has nevertheless been able to avert three major famines in Greece, Yugoslavia and Austria.

Campaign on Lemke Antivivisection Bill Renewed

The newspaper campaign in favor of the Lemke bill to forbid vivisection of dogs in the District of Columbia has been renewed by a publication favoring such legislation. Representative Miller, Republican of Nebraska, chairman of the House District of Columbia subcommittee on health and education, predicted action on the bill shortly. Committee members accompanied by reporters and photographers recently toured medical laboratories here.

First Survey of Cancer Cases in District of Columbia Area

A comprehensive cancer control program for the District of Columbia is expected to result from the overall survey of cancer cases which was launched this week. Informational blanks have been mailed to all local doctors and hospital heads to ascertain how many District of Columbia residents are under treatment or observation for cancer. The survey will use methods similar to those used in Atlanta, New Orleans, San Francisco, Dallas, Philadelphia and other large cities.

Dr. Marchetti Takes over Combined Georgetown Departments of Obstetrics and Gynecology

Dr. A. A. Marchetti, associate professor at Cornell University Medical School, is to take charge of the combined departments of obstetrics and gynecology of Georgetown University Medical School on July 1. The two former part time department heads who are retiring July 1 are Dr. J. J. Mundell, obstetrics, and Dr. Leon A. Martel, gynecology. Dr. Marchetti was born in Richmond, Va., and graduated from the University of Richmond and Johns Hopkins University.

Veterans Seeking Medical Care Urged to Identify Themselves

Ex-service people applying at Veterans Administration regional offices for medical treatment, hospitalization or care in a VA home should take along needed identifying documents in order to assure speedy, efficient service for themselves. Officials explain that many veterans daily applying for hospital or medical care appear without necessary identification.

Medical Legislation

STATE LEGISLATION

Delaware

Bills Introduced.—H. 222 proposes to authorize the mayor and council of New Castle to levy **occupational taxes** on business and professions carried on within the city. S. 285 **proposes to require every physician** to submit to an annual examination and test for venereal disease and to display a certificate showing the results of such examination in a prominent place in his office. S. 305 proposes to authorize the use in any criminal prosecution relating to **driving a motor vehicle** under the influence of intoxicating liquor of a chemical analysis of the defendant's blood. S. 341 proposes to make it unlawful for any person to teach or disseminate any information whatsoever or doctrine or principle relating to **artificial control of birth** of human beings.

Idaho

Bills Passed.—H. 219 passed the house March 4 It proposes an enabling act for the formation and **regulation of nonprofit corporations** organized to render medical, surgical and / or hospital service on a membership fee plan. S. 102 passed the house March 3. It proposes an enactment of a state **hospital survey and construction act** requiring a statewide survey of hospital facilities and the preparation of a program for the construction of additional facilities. The proposal would also require the appointment of an advisory hospital council and would authorize the commissioner of the state department of public health to apply for and accept federal funds to assist the state in survey and construction activities.

Bills Enacted.—H. 141 has become chapter 167 of the Laws of 1947. It **adds cancer** to the list of diseases which a physician must immediately report to the department of public health. H. 144 was approved March 10. It limits the **sale of barbituric acid** or compounds to sale on a prescription signed by a person licensed to prescribe or administer barbiturates. S. 54 has become chapter 132 of the Laws of 1947. It repeals the existing law relating to the licensing of **lying-in hospitals.** S. 55 has become chapter 133 of the Laws of 1947. It provides for the licensing, inspecting and **regulating of all hospitals** within the state.

Illinois

Bill Introduced.—H. 183 proposes to authorize each county in the state to levy a **tax for the treatment** and care of persons afflicted with poliomyelitis and authorizes the appointment within each county which levies such tax of a board to arrange for the necessary care and treatment of persons so afflicted by contract with public and private hospitals in the state.

Indiana

Bills Enacted.—S. 1 has become chapter 173 of the Laws of 1947 To amend the law relating to **hospital surveys,** it appoints the state board of health as the state agency to cooperate with the federal government in the construction of hospitals within the state and adds to the hospital survey law a new section defining the terms "hospital," "public health center" and "nonprofit hospital." S. 212 has become chapter 253 of the Laws of 1947. It amends the medical practice act by authorizing the board of medical examiners to grade questions given by the **National Board of Medical Examiners** and to accept examinations certified by the National Board as the examination given to the applicant. This enables an applicant to be licensed in Indiana without having to wait until the regular examination given by the Indiana board occurs. S. 213 has become chapter 254 of the Laws of 1947. It provides for the **annual registration** of all persons holding an unrevoked license to practice the healing art in any form or manner.

Iowa

Bills Introduced.—H. 431 proposes to authorize any peace officer to take a blood, urine, breath or body substance **test to determine intoxication** of any person under arrest for any crime in which the issue of intoxication may arise and to admit the results of such tests in evidence in court hearings. The proposal would further provide that the test specimen for analysis may be taken irrespective of the want of consent of the person under arrest, and the doctor-patient privilege shall not be applicable to giving evidence of the test in court. H. 465 proposes a hospital licensing law.

Montana

Bills Enacted.—H. 235 has become chapter 269 of the Laws of 1947. It provides for the licensing and **regulating of hospitals** within the state and prohibits the discrimination between the patients of any licensed physician on the ground that the physician is not a member of the medical or surgical staff of the hospital. It exempts from its terms Christian science institutions. H. 236 has become chapter 270 of the Laws of 1947. It is the Montana **Hospital Survey and Construction Act,** requiring a survey of hospital and health facilities in the state, a program of construction for additional needed facilities, the appointment of an advisory hospital council and the necessary cooperation for the receiving of federal funds to aid in the construction of such additional needed facilities as the program may require. H. 314 has become chapter 192 of the Laws of 1947. It provides for the licensing and **regulating of boarding homes** or nursing homes for the aged. S. 100 has become chapter 208 of the Laws of 1947. It provides that each **applicant for a marriage license** shall present a certificate signed by a duly qualified physician licensed to practice medicine and surgery in any state or United States territory or any person authorized by the laws of Montana to make such certificate certifying that the applicant has been given an examination for the discovery of syphilis.

Nebraska

Bill Introduced.—Bill No. 408 was previously reported as proposing to amend the section of the medical practice act referring to examinations so as to **exempt chiropractors** therefrom. This was an error. The proposal, actually, is to exempt chiropractors from the provisions of the basic science act.

Bill Passed.—Bill No. 160 passed the legislature March 6. It proposes the enactment of a state **hospital survey and construction act** which would require the department of health to make an inventory of existing hospitals and to develop and administer a state plan for the construction of necessary additional hospitals. The proposal would also provide for compliance with the requirements of the federal hospital survey and construction act and regulations thereunder.

Nevada

Bills Introduced.—A. 160 proposes the enactment of a **basic science law** requiring all persons desiring to be licensed to practice the healing art or any branch thereof to obtain first a certificate of ability in anatomy, physiology, chemistry, bacteriology and pathology. A. 185 proposes to require each applicant for a **marriage license** to file a certificate executed by a duly licensed physician stating that such applicant is free from syphilis in a communicable stage. A. 199 proposes the enactment of a hospital licensing law.

Bill Passed.—S. 55 passed the senate March 5. To amend the medical practice act, it proposes to authorize the state board of medical examiners, in its discretion, to issue permits to any properly qualified applicant **to serve as resident medical officer** in any hospital in Nevada subject to certain provisions. Such temporary licentiate would be authorized to practice medicine only within the confines of the hospital specified in his permit and the permit would in no case be in excess of one year, renewable at the discretion of the board of medical examiners.

New Jersey

Bill Introduced.—A. 220 proposes the creation of a New Jersey **state board of naturopathic examiners** and defines naturopathy as "the prevention, diagnosis and treatment of human ailments and diseases by means of any one or more of the psychological, physical or mechanical, chemical or material forces of nature, excluding drugs, surgery or other artificial measures." The proposal would authorize licentiates to "have the authority to examine patients, diagnose and treat by natural agencies any disease pain, injury, deficiency, deformity ailment or physical or mental condition and to prescribe and regulate the patient's dietary, sanitary and hygienic requirements, also use the x-ray and any other instrument for the purpose of diagnosing, analyzing and determining the patient's ailment, . . .'

New Mexico

Bills Introduced—S 160 proposes the enactment of a **hospital licensing law** S 246, to amend the **workmen's compensation act**, proposes to authorize an employer or insurer to be entitled to have a physical examination of any claimant by a physician of his own choice subject to the furnishing of reports subject to the requirement that the physician be qualified to practice medicine under the laws of this state or the state wherein the claimant resides and subject to certain other requirements .

Bills Enacted—S 51 was approved March 12 It **defines a clinic** as an establishment where patients are admitted for special study and treatment by a group of physicians practicing together and provides that no person or group of persons shall use the word clinic in connection with any establishment or office which does not come within such definition S 52 was approved March 12 It requires all **persons licensed to practice** any of the healing arts to designate clearly the school of medicine or practice which such person is licensed to engage in and provides that failure to comply with such restriction shall constitute unprofessional conduct

New York

Bills Introduced—A 2012 and S 1839 propose the creation of a **state board of chiropractic examiners** and define chiropractic as 'the science of locating and the removing of nerve interference in the human body, according to chiropractic principles, where such interference is *the result of or caused by misalignment or subluxations of the vertebral* column It excludes operative surgery, the reduction of fractures the prescription or use of drugs or medicine and the practice of obstetrics" A 2305 proposes the creation of a **board of massage examiners** and defines massage as 'the stroking kneading tapping or rolling with the hands, or with other instrumentalities of the human body for hygienic or remedial purposes for the purposes of relieving, alleviating or reducing affected parts thereof but shall not include reduction of a fracture or dislocation of a bone"

Bill Passed—S 1904 passed the senate March 4 To amend the penal law with respect to **animal experimentation**, it proposes to eliminate therefrom the existing exception in favor of experiments performed under the authority of the faculty of some regularly incorporated medical college or university of the state Under the proposal such institutions would also have to obtain approval from the state commissioner of health prior to conducting any experiments

Oklahoma

Bill Introduced—S 145 proposes the creation of a **board of examiners for naturopathy** and defines naturopathy as "the diagnosis and practice of physiological and material sciences of healing, as defined by an Act of Congress approved February 7, 1931, as follows The physiological and mechanical sciences such as mechanotherapy, articular manipulation corrective orthopedic gymnastics neurotherapy, psychotherapy, hydrotherapy and mineral baths electrotherapy, thermotherapy, phototherapy chromotherapy, vibrotherapy, thalamotherapy and dietetics which shall include the use of foods of such biochemical tissue-building products and cell salts as are found in the normal body, and the use of vegetable oils and dehydrated and pulverized fruits flowers seeds barks roots and vegetables uncompounded and in their natural state, and, added to the above definition will include all methods now in use, as physiotherapy, Indian Herb, Herb and Simple Remedy doctoring physical culture, gynocology, autobiochemistry, colonic therapy and scientific massage and such *methods as are taught in standard schools* of Naturopathy"

South Dakota

Bills Enacted—H 50 was approved March 8 It is a South Dakota **hospital survey and construction act** Among other things this law requires any institution accepting federal funds for construction purposes to agree first that it will not discriminate between practitioners of the various healing arts and every duly licensed doctor of medicine, osteopathic physician and chiropractor shall have the right to and shall be entitled to practice his profession in any such hospital which has received federal funds H 302 was approved March 5 It **amends the basic science act** by exempting therefrom any one who has served as a medical officer in World War II S 184 was approved March 10 It prohibits the **sale of barbiturates** *except on the original prescription* of a practitioner, defined as a person licensed by law to prescribe and administer barbiturates

GOVERNMENT SERVICES

ARMY

RESEARCH IN MILITARY MEDICINE

The War Department has announced details of its plans for military medicine in its research and development program for 1947:

In order for progress to continue, it is essential that further research be carried out in all the present research fields and that special emphasis be placed on:

Traumatic surgery. Great progress has been made in this important field during the war years. The Army offers unusual opportunity for further research in this most important field of surgery.

Psychoneurosis. This field offers great promise in research and possible saving of great manpower losses to the Army. There were 642,351 cases of psychoneurosis in the Army during the past war, representing a tremendous manpower saving if methods for reducing the numbers of these cases can be developed.

Radiation casualties. The relationship of projects dealing with atomic energy and medical problems related thereto must be established in order to afford the Medical Department opportunity to determine treatment methods for both the acute and the chronic effects, to study the chronic pathologic conditions following radiation and to determine protective methods. Preliminary work in this line is now being carried out.

Cold weather operations. The fact that 50,000 casualties due to cold were suffered in one year in the past war is adequate proof that further research is necessary. A great deal of research in physiology, chemistry and pathology is needed in this field. The Quartermaster Corps shares in this important research field in the development of cold weather clothing and other protective equipment.

Special disease problems. This includes research in prevention, control and treatment of such conditions as respiratory infections, intestinal disease, infectious hepatitis, malaria, plague and venereal disease.

Antibiotics. Research must be continued for the development of new agents such as penicillin and streptomycin and for improved methods for the use of such agents.

Immunization. Efforts to find new or improve present immunizing agents should be continued. In addition, a great deal of research is necessary in the field of natural immunity and its development.

Physical standards. A considerable amount of research should be directed toward proper evaluation of physical standards for certain types of work. This may well result in a great reduction of arbitrary manpower loss because of minor physical deficiencies.

Wound ballistics. Research should be continued in order to evaluate properly types of wounds produced, their treatment and causes of remote trauma.

Medical equipment. The development of improved means of offering the best medical care to the soldier in the field is a never ending research project.

Medical and surgical practice. There are numerous unsolved problems in the prevention, control and treatment of many medical and surgical diseases. Owing to the military control exercised over patients, the Army has a great opportunity to carry out extensive studies in this direction.

AVIATION MEDICINE

Many research projects must be carried out in order to keep abreast of engineering developments and to determine the maximum performance of average men so that this may be used as a baseline for designing engineers to work from. Some of the more important categories of research in aviation medicine are:

Safety and survival methods and devices. Research in this broad and important field includes projects on various types of oxygen masks and their accessories, projects on various types of life vests, life rafts, radio and other signal devices, distillation apparatus, fishing equipment and devices to detect radioactivity.

Escape mechanisms and methods. Many important projects are being carried out on escape from high speed and high altitude airplanes, including ejector type seats, pressurized suits and oxygen masks.

Acceleration and deceleration and gravity. In this broad category research is being carried out on the effects of acceleration and deceleration of the body in various positions, on the development of antigravity mechanisms and devices, and on the effects of gravity on the human body.

Physiology. Important research projects in the physiology of anoxia, resuscitation, high altitude flying and high speed flying must be continued.

Heat and cold. The human tolerance to heat and cold in various situations and environments is being carried out in certain projects. This is similar to many studies carried out for the Army ground forces by the Surgeon General at Fort Knox, Kentucky.

Psychology. In this most important field research is being carried out on the psychologic factors involved in aircraft control instruments, in legibility of indicators, in speed of comprehension of instrument panels, in reaction to blind flying and many others.

Radiation effects. The Air Surgeon and the Surgeon General have very broad interests in this field. The Air Surgeon is especially interested in the field of instrumentation for the detection of radioactivity at high speeds, high altitudes and low temperatures. Research must be done for the protection of personnel in flight when fission clouds are encountered.

ASSIGNMENT OF PRIMARY COGNIZANCE

Primary cognizance in the field of military medicine is assigned to the Surgeon General. Responsibility for those phases which are peculiarly applicable to the problem of flight is assigned to the commanding general, Army Air Forces.

ARMY AWARDS AND COMMENDATIONS

Colonel John I. Brewer

The Legion of Merit has been awarded to Col. John I. Brewer, M. C., A. U. S., Chicago, for service with the Army Air Forces Convalescent Center, Buckley Field, Colorado, from January 1944 to May 1944 and headquarters, Army Air Force Personnel Distribution Command, from February 1945 to October 1945. He organized and directed the facilities for rehabilitation and convalescent care of the disabled and hospitalized personnel of the Army Air Forces in which activities, said the citation, his initiative, foresight and administrative skill were largely responsible for the success of that program. Dr. Brewer graduated from Rush Medical College in 1928 and entered military service July 17, 1942.

Captain Richard G. Hodges

The Legion of Merit has been awarded to Capt. Richard G. Hodges, M. C., A. U. S., of Cleveland, who as director of pneumonia research and epidemiologist, Sioux Falls Army Air Field, during the period from July 8, 1943 to Oct. 1, 1945. Captain Hodges conducted an investigation of the prevention of pneumococcic pneumonia which led to the unequivocal proof that pneumonia vaccination is feasible. The citation made note of the fact that Captain Hodges' distinctly meritorious contribution to medical science reflects great credit on himself and on the armed forces of the United States. Dr. Hodges graduated from Harvard Medical School in 1936 and entered military service on Dec. 31, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Commander Richard D. Anderson

The Navy Commendation Ribbon was recently awarded to Commander Richard D. Anderson (MC), U.S.N.R., of Burlington, N. J. The citation signed by Admiral H. K. Hewitt was as follows: "As senior medical officer you carried out your duties in a cool and competent manner under intermittent enemy shell fire during the first week of the Normandy invasion in June 1944 and thereafter under sporadic night enemy bombing. Landing first at Omaha Beach on D plus 2, you cared for the wounded after the unusually heavy bombing of that night. Arriving at Utah Beach the following day you immediately organized their medical care in addition to assisting at a nearby army hospital in caring for both Army and Navy wounded. By your efforts and diligence you were responsible for preventing the spread of disease and by your professional skill aided in reducing the number of fatalities. I commend you for splendid devotion to duty and outstanding professional ability under fire, which reflect credit on yourself and on the United States Naval Service." Dr. Anderson graduated from the University of Virginia in 1917 and entered the military service April 21, 1942.

Dr. James Edgar Paullin

The President of the United States recently awarded the Medal for Merit to Dr. James Edgar Paullin of Atlanta, Ga. The citation signed by President Truman specifies exceptionally meritorious conduct in the performance of outstanding services to the United States since 1943 and explains that Dr. Paullin served as honorary consultant to the Bureau of Medicine and Surgery of the Navy Department while also serving as a member of the directing board of the Procurement and Assignment Service of the War Manpower Commission during a period when the solution of problems of vital importance to the successful conclusion of the war required the intensive and unremitting efforts of all concerned. By his self sacrifice and the employment of his high professional prestige, his talents as a physician and surgeon, and his abilities for successful organization of professional groups, he rendered the most responsible, notable and distinguished service. To the Navy directly, through his contributions as honorary consultant, and to all of the armed services through his achievements with the War Manpower Commission, Dr. Paullin's advice and direction were of exceptional and invaluable aid and assistance.

MISCELLANEOUS

PHYSICIANS WANTED FOR CIVIL SERVICE

The U. S. Civil Service Commission has announced an examination for filing medical officer positions. These positions are located in various federal agencies, in Washington, D. C., in the U. S. Public Health Service and the Indian Service throughout the United States and in the Panama Canal Zone. Salaries range from $4,149 to $5,905 a year, with higher salary rates for the Canal Zone positions. No written test will be given. To qualify, all applicants must be graduates of a medical school of recognized standing and must also meet other requirements, which include experience and training in the field of medicine. The age limits are 45 years for Panama Canal Zone positions and 62 years for other positions. These age limits are waived for persons entitled to veteran preference (up to the age of 62 for the Panama Canal Zone Service and without limitation for other agencies). Interested persons may secure information and application forms from most first and second class post offices, from Civil Service regional offices or from the U. S. Civil Service Commission, Washington 25, D.C. Applications must be filed not later than April 22, 1947.

SALE OF SURPLUS TRANSFUSION SETS

About 140,000 sets of blood transfusions apparatus, acquired by the army at a cost of about $125,000, will be offered for sale as surplus on a competitive bid basis. Bids will be accepted by the War Assets Administration regional offices holding inventories, New York, Chicago and San Francisco, from April 10 to April 30.

The sets are unused army field models of the indirect recipient type designed to be used once and then destroyed. Each set consists of a sealed-in metal tube with glass filter housing, metal filter, a 3½ foot length of rubber tubing, an 18 gage, 1½ inch recipient needle and a 17 gage 1½ inch airway cannula needle. Use of this apparatus requires a donor set or a supply of blood as in a blood bank for complete transfusions.

Samples may be inspected at regional offices holding inventories. The New York City region has 65,952 sets, Chicago 44,900 and San Francisco 28,224. Priority claimants, such as state health agencies, may submit letters of intent to buy. All levels of trade, including hospital supply houses, manufacturers and exporters, are invited to submit bids for part or the entire lot in each region.

SALE OF SURPLUS DRUGS

Offerings consisting of $300,000 worth of surplus chemicals and pharmaceuticals, $180,000 worth of parenteral solutions and $150,000 worth of Sulfasuxidine (succinylsulfathiazole) tablets are announced by the War Assets Administration.

All three offerings are at fixed prices f. o. b. location of inventories. The chemicals and pharmaceuticals are located in Cincinnati, Denver, Louisville, New York, Richmond, San Francisco and St. Louis. Sulfasuxidine inventories are in San Francisco and St. Louis. Orders for any of the items should be sent in duplicate to the Director, Medical Sales Division, War Assets Administration, Washington 25, D. C. Complete descriptions and price listings may be obtained on request to the same address.

The chemicals and pharmaceuticals include mercury bichloride tablets in bottles of 250 each; protein silver, mild and strong, 4.6 grain, in bottles of 100; iodine crystals in ¼ pound bottles; glyceryl trinitrate 1/400 grain hypo in tubes of 20 units. The Sulfasuxidine tablets, 7.7 grains, are packaged 1,000 to the bottle.

The chemicals, pharmaceuticals and Sulfasuxidine tablets are being offered concurrently to priority claimants and other buyers. Ten per cent of the Sulfasuxidine tablets have been reserved to fill federal agency orders received by 5 p. m. March 24; 10 per cent of the chemicals and pharmaceuticals have been reserved for federal agency orders received by 5 p. m. March 25. Other orders for these items received by the same dates will be filled in the following sequence: (1) certified veterans of World War II; (2) other priority claimants in the usual sequence; (3) other buyers. In addition, orders received later will be filled without regard to priorities.

The parenteral solutions include sodium citrate in ampules, vials and bottles, sodium cacodylate 1 grain ampules and caffeine with sodium benzoate in ampules. All have been passed by the Food and Drug Administration and are offered at less than acquisition cost to all levels of trade, including exporters. This offering will close March 25. Inventory is located in St. Louis, New York, Cincinnati, Atlanta, Ga., Richmond, Va., and Louisville, Ky.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ALABAMA

State Meeting at Birmingham.—The annual session of the Medical Association of the State of Alabama will be held in Birmingham April 14-16 at the Thomas Jefferson Hotel under the presidency of Dr. Carl A. Grote, Huntsville. In addition to papers by members of the association the program will include those on Tuesday by Drs. Winfield K. Sharp Jr., U. S. Public Health Service, Washington, D. C., on "The Part Played by Alabama Physicians in the Development of Public Health"; C. Allen Good Jr., Mayo Clinic, Rochester, Minn., "Importance of Follow-Up Roentgenograms in Pulmonary Diseases"; Alvert Weinstein and Cobb Pilcher, Nashville, Tenn., "Management of Hypertension, with Particular Reference to the Surgical Treatment"; Reginald Fitz, Boston, the Jerome Cochran Lecture, and Oscar T. Clagett, Mayo Clinic, Rochester, "Surgical Management of Gastric and Duodenal Ulcers." The alumni banquet of the University of Alabama School of Medicine will be held Tuesday evening. Among the speakers will be Dr. Harrison H. Shoulders, Nashville, Tenn., President, American Medical Association. The session will close with a business meeting of the association sitting as the board of health of the state of Alabama.

CALIFORNIA

New Program for Treatment of Mental Diseases.—The state of California has embarked on a new program for the prevention and treatment of mental diseases. Preparations are already under way for construction of several mental institutions and the modernization of existing facilities. The department of mental hygiene has established clinics in Los Angeles and San Francisco, and Governor Earl Warren has advocated their expansion in San Diego, Fresno, Sacramento and other communities. Dr. Lawrence Kolb, Sacramento, former chief, mental hygiene division, U. S. Public Health Service, has been appointed deputy director, medical, to develop a program of raising treatment standards and to promote mental health in the community. A new position of director of clinical services has been established at each one of the state mental institutions. No administrative responsibilities are attached. At present positions are available in the department for physicians and surgeons, psychiatrists and clinical directors with salaries ranging from $345 to $715 a month. Veterans will receive special consideration. Out of state physicians may practice in California mental institutions for one year before receiving their California license. Address inquiries to F. E. Kline, State Personnel Board, 401 State Building, Los Angeles.

CONNECTICUT

Society News.—On Tuesday, April 8, Dr. Morris Fishbein, editor of The Journal, will address members of the Fairfield County Medical Association at their annual meeting, Hotel Stratford, Bridgeport. The following evening Dr. Fishbein will speak at the 100th anniversary meeting of the Central Medical Society, Middletown.

Personal.—Dr. R. Glen Urquhart, Norwich, has been appointed to the staff at St. Francis hospital, Hartford, as consultant in diseases of the chest. Dr. Urquhart has been in private practice since his retirement a year ago as chief surgeon to the five state sanatoriums.——Dr. C. Frederick Yeager, Bridgeport, is the physician for the Remington Arms Company, Inc., Bridgeport, rather than the Remington Rand Company, as stated in The Journal, March 8, page 706.

GEORGIA

Changes in Health Officers.—Dr. Clarendon B. Woods, Washington, D. C., has been appointed health officer for Hampton and Colleton counties with headquarters in Walterboro. Dr. John D. Stillwell, Waycross, has been transferred from the regional office to the state health department in Atlanta as assistant director of local health organizations, replacing Dr. Harald M. Graning, recently recalled from Georgia by the U. S. Public Health Service for assignment to cancer control activities. Dr. Stillwell, a graduate of Northwestern University Medical School, 1927, entered public health work in Georgia in 1938 as commissioner of health in the Telfair-Wheeler District Health Department, where he remained until beginning regional duties in 1940.

ILLINOIS

Increase in Diphtheria Deaths in 1946.—The Illinois Department of Public Health reports the doubling of deaths from diphtheria in 1946 over 1945. The disease caused 13 deaths in 1946 among children under 5, as opposed to 6 in 1945 in the same age group. The 9 deaths among children 5 to 14 were 3 more than for those ages during 1945. The department also reports an increase in diphtheria among adults, with 9 deaths in persons 15 years and over as opposed to 3 in 1945.

Two More New Sewerage Systems.—Dr. Roland R. Cross, director, Illinois Department of Public Health, Springfield, and chairman of the sanitary water board, has issued a permit to the city of Louisville for construction of a new sewer system and sewage treatment works, with an outlet into Little Wabash River. A permit was issued also to Washington, Tazewell County, for the construction of a new sewer system, including a modern sewage treatment plant. These make twelve permits issued to date this year by the state sanitary water board for the construction of sewage disposal facilities by municipalities.

Chicago

Bequest to St. Luke's.—Under the will of Mrs. Emily Lyon Gary, formerly of Glencoe, widow of the late John W. Gary, investment banker, St. Luke's Hospital will receive $225,000 in direct bequests and other bequests which will total $275,000. Mrs. Gary died February 18.

Special Society Elections.—At its annual meeting, February 17, the board of trustees of the Hektoen Institute for Medical Research of the Cook County Hospital elected as directors Britton I. Budd, Chester Davis, William N. Erickson, Donald M. Nelson, Guy E. Reed and Daniel Ryan.

Annual Lecture on Medical History.—The fourth annual D. J. Davis Lecture on Medical History will be delivered by William S. Middleton, dean, University of Wisconsin Medical School, Madison, April 9, in room 221 of the University of Illinois College of Medicine. The subject will be "Wisconsin Men in Chicago Medicine."

Meeting on Isotopes and Radioactive Iodine.—At a meeting of the Chicago Medical Society Wednesday, April 26, in the John B. Murphy Memorial Auditorium, 8 p. m., Dr. John H. Lawrence, head of the division of medical physics, University of California Medical School, Berkeley-San Francisco, will speak on "The Use of Isotopes in Medical Investigation." Dr. Mayo H. Soley, assistant dean, University of California Medical School, will speak on "Radioactive Iodine in the Treatment of Toxic Goiter." The meeting will be preceded by a dinner in honor of the guest speakers at the Drake Hotel, 5:30 p. m.

IOWA

Fly Control Conference.—At a recent meeting of the State Fly Control Conference, preparations were made for an extensive campaign in 1947. Active community groups and local farm organizations are included in promotion of the campaign. Last year's campaign, carried out in Ames, Manchester, Maquoketa, Traer, Dysart and Winthrop, proved highly successful.

Committee for Study of Venereal Diseases.—At the first meeting of the Iowa Committee for the Study of Venereal Diseases, appointed jointly late in 1946 by the state medical society and the state department of health, it was recommended that the Iowa State Department of Health institute uniform procedures so that proper evaluation of the effectiveness of treatment schedules for the rapid treatment of syphilis might be made. The committee was formed to act as a clearing house for information on all phases of venereal disease diagnosis, treatment and control. The problem will be studied with a view toward making suggestions and recommendations to foster complete cooperation between the physicians of Iowa, the state department of health, the State University of Iowa College of Medicine, Iowa City, and other interested groups or agencies in order to obtain the ultimate in scientific diagnosis, treatment and control.

KENTUCKY

Eastern Medical Association.—At a meeting of the Eastern Kentucky Medical Association in Paintsville February 27 nine counties were represented in the attendance. Officers elected for the coming year were Drs. Clyde C. Sparks, Ashland, president; James C. Preston, Pikeville, vice president, and John G. Archer, Prestonburg, secretary. Among the speakers were Drs. John W. Moore, dean, University of Louisville School of Medicine; John A. Caldwell, clinical professor of surgery, University of Cincinnati; R. Arnold Griswold, professor and head of the department of surgery, University of Louisville; Walter C. Swann, Huntington, W. Va.; Howard E. Dorton, Lexington, and Philip E. Blackerby, commissioner of health, Louisville.

LOUISIANA

Annual Lecture.—Dr. William Dock, professor of medicine, Long Island College of Medicine, Brooklyn, delivered the annual lecture of the honorary medical society of the Louisiana State University School of Medicine, New Orleans, February 25, at Charity Hospital, on proteinuria and edema.

MARYLAND

Cancer Control Program.—The Maryland division of the American Cancer Society, in coöperation with the state health department and various county medical societies, announces that cancer detection centers have been opened at the University of Maryland Hospital and at the Johns Hopkins Hospital. Within the next year several additional centers will be opened in hospitals in Baltimore City and in the counties of the state. Tumor conferences are being conducted at various locations. Two pathologic laboratories have been established and containers for specimens have been distributed throughout the state. The pathologic report is sent to the physician by mail or telephone. The American Cancer Society will assist the medically indigent with complete coverage.

MASSACHUSETTS

University News.—Harvard Medical School announces the appointment of nineteen new members to the teaching staff, including assistants in various departments, fellows and research fellows. Among those appointed are Alexander Terzin, Belgrade, Yugoslavia, research fellow in bacteriology and immunology; Suzanne T. van Anerongen, Amsterdam, the Netherlands, assistant in psychiatry; Pen-Chung Yu, Kweiyang, Kweichow, China, research fellow in bacteriology and immunology, and Dora G. Mittelman, Buenos Aires, Argentina, research fellow in physical chemistry.

NEW YORK

Chairman of Public Health Council.—Dr. L. Whittington Gorham, Albany, has been named chairman of the state Public Health Council. Dr. Gorham, a graduate of Johns Hopkins University School of Medicine, Baltimore, has for ten years been director, department of medicine, Albany Medical College and physician in chief on the staff of the Albany Hospital.

Appoint Tuberculosis Field Assistant.—Mr. Earl J. Winters, formerly chief technician of the x-ray service of the Cuyahoga County Tuberculosis Clinic, Cleveland, has been appointed field assistant of the New York Tuberculosis and Health Association's chest x-ray service. Mr. Winters will schedule the association's mass x-ray projects and will emphasize extension of this work among business and industrial concerns in Manhattan. During 1946 more than 24,000 individuals were x-rayed in Manhattan, the Bronx and Richmond under the association's x-ray program conducted in cooperation with the department of health.

Facilities for Care of Advanced Cancer Patients.—Establishment of facilities for the care of cancer patients in advanced stages of the disease was announced in January by Julius J. Perlmutter, president of the National Cancer Foundation. The facilities consist of a unit of 125 beds at Manhattan General Hospital maintained by the foundation and supervised by physicians of the National Medical and Scientific Council of the foundation. The foundation plans to establish special hospitals, to be known as Hope Institutes, in other communities. Beds in the cancer unit will be available to cancer patients regardless of economic status, Mr. Perlmutter said. Application can be made through the patient's physician, through accredited social service agencies or by direct application to the medical Social Service Division of the National Cancer Foundation, 85 Franklin Street.

New York City

Site for New Metropolitan Hospital.—An entire block on the East Side was acquired in February as a site for the new Metropolitan Hospital, the New York *Times* reports. It extends from First to Second Avenue from Ninety-Eighth to Ninety-Ninth Street. Negotiations are under way for further property to complete the site. The new hospital, which will replace the present Metropolitan Hospital on Welfare Island, will have a capacity of 750 beds, with the upper floors devoted to a self-contained unit of 250 beds for tuberculous patients.

Rosenstock Memorial Awards.—The Rosenstock Memorial Foundation, Inc., offers fellowships of $2,000 a year for medical research in hospitals with medical school affiliations in the city. Fellowships are limited to those who apply within three years of completion of internship or residency. Recipients recently announced are Drs. Doris J. W. Escher for research in edema at Montefiore Hospital for Chronic Diseases, Raymond S. Megibow for research in hypertension at Mount Sinai Hospital and Alan Erslev for research in leukemia at Memorial Hospital.

Alfred E. Smith Memorial Wing.—The Civilian Production Administration has announced approval of the construction of a $1,569,900 Alfred E. Smith Memorial Wing of St. Vincent's Hospital. The addition, to be finished in about a year and a half will accommodate more than 118 beds, according to the New York *Sun*. A campaign to construct a hospital, "a living memorial perpetuating Alfred E. Smith's services to his fellow man," was launched in October 1945 on the first anniversary of former Governor Smith's death (The Journal, Oct. 20, 1945, p. 563).

Dedicate Memorial Plaque.—At a ceremony March 5 the employees of Kings County Hospital, Brooklyn, dedicated a memorial plaque to 816 employees who served during World War II, 9 of whom died in service. Among the speakers at the program were Dr. Joseph Tenopyr, president of the hospital's medical board; Col. George G. Dixon, M. C., Brooklyn, former chief of surgery; Col. Arthur Fankhauser, M. C., Brooklyn, former chief of medicine, 37th General Hospital, U. S. Army, and Dr. Edward M. Bernecker, commissioner, department of hospitals, City of New York.

New Blood Donor Service.—The American Red Cross, in cooperation with the Coordinating Council of the Five County Medical Societies of Greater New York, will establish a civilian blood donor service within the next month. Donor stations will be established at 401 Fifth Avenue and 57 Willoughby Street, Brooklyn, wartime blood donor service points. The project will make available whole blood for transfusions and research and also blood derivatives for various uses. The existing blood and plasma exchange, a nonprofit agency serving metropolitan hospitals, will be supplemented, not replaced. Patients in five municipal hospitals, Bellevue, Kings County, Morrisiania, Queens General and Sea View, will be the first to benefit by the new program. Expansion of the coverage is expected to include additional city hospitals and voluntary institutions. The blood and blood derivatives made available will be free, but if the program is extended to voluntary hospitals a laboratory service charge will be made, although the blood itself will be free.

NORTH CAROLINA

Personal.—Frank G. Hall, Ph.D., Duke University School of Medicine, Durham, has returned from Germany, where he spent two and one-half months at the request of the Army Air Forces investigating German scientists and their wartime research in the field of aviation medicine.

Director of State Tuberculosis Sanatoriums.—The board of directors of the North Carolina tuberculosis sanatoriums has selected Dr. Henry S. K. Willis, superintendent at the William H. Maybury Sanatorium, Northville, Mich., as superintendent of the three state institutions, succeeding the late Dr. Paul P. McCain. Dr. Willis is a graduate of the University of North Carolina and also of Johns Hopkins University School of Medicine, Baltimore.

OREGON

University News.—Dr. Numan W. Karr has been appointed assistant professor in the department of pharmacology, University of Oregon Medical School, Portland. Dr. Karr received his Ph.D. at the University of California and his M.D. from the University of California School of Medicine, Berkeley-San Francisco. For the past two years he has been on active duty with the navy.

Memorial Lectures.—The Ernest A. Sommer Memorial Lectures will be given at the University of Oregon Medical School, Portland, April 2-4 in conjunction with the Alumni meeting of the University of Oregon Medical School. Guest lecturers will be Drs. Karl F. Meyer, director of the George Williams Hooper Foundation, the Medical Center, University of California, Berkeley-San Francisco; Philip S. Hench of the arthritis section, Mayo Clinic, Rochester, Minn., and Frederick H. Falls, professor and head of the department of obstetrics and gynecology, University of Illinois College of Medicine, Chicago.

PENNSYLVANIA

Industrial Health Conference at Williamsport. — The Central Pennsylvania Industrial Health Conference will be held in Williamsport April 23. Among subjects to be discussed are mass x-ray in industry, health education in industry, how a plant medical service can help industry and how to secure a plant medical program. At a round table discussion on the benefits of an industrial health program representatives of the employee, the employer, the industrial physician, the industrial hygienist, the insurance carrier and the nurse will participate. In addition, the state industrial health bureau will have an exhibit.

Tuberculosis Case Register. — The Tuberculosis and Health Society of Dauphin and Perry Counties has organized a central tuberculosis case register, a result of a meeting Jan. 14, 1945 of representatives of various health groups and private physicians. The register has received the approval of governors of Dauphin County Medical Society and of the Pennsylvania Department of Health. The register contains information regarding all known cases of tuberculosis, including names and locations of patients, diagnosis, medical supervision and household contacts from the beginning to the end of observation. This information was assembled with the assistance of the Pennsylvania Tuberculosis Society and the advice of the case register consultant of the National Tuberculosis Association.

Meeting of Tumor Clinic Association.—Dr. Stanley P. Reimann, Philadelphia, chairman, Cancer Commission, Medical Society of the State of Pennsylvania, and Dr. Danib Pfeiffer, chief surgeon at Abington Memorial Hospital, Abington, will speak on the causes, early diagnosis and modern treatment of cancer at a meeting of the Wainwright Tumor Clinic Association in the Women's Club Auditorium, Allentown, April 8 to which the public is invited. A discussion period open to questions from the public will follow. The association, named in honor of the late Dr. Jonathan Wainwright, Scranton, will hold two scientific sessions during the day, a morning session at the Allentown Hospital and one in the afternoon at Sacred Heart Hospital. At the morning session Dr. George R. Moffitt, Harrisburg, will speak together with Drs. William C. Troxell, Willard C. Masonheimer, C. Merrill Leister and Martin S. Kleckner, all of Allentown. Dr. J. Rudolph Jaeger, neurosurgeon at Jefferson Medical College of Philadelphia, will be guest speaker at the afternoon meeting along with Drs. Donald Stader, Latrobe, Leo T. Chylack, Charles L. Mengel and J. Frederic Dreyer, Allentown. The Lehigh County Medical Society is sponsoring the evening meeting.

TEXAS

University News.—Dr. Frederick E. Mohs, University of Wisconsin Medical School, Madison, gave a demonstration on the chemosurgery of cancer at the University of Texas Medical Branch, Galveston, March 8. Dr. Lester R. Dragstedt, professor of Surgery, University of Chicago School of Medicine, gave a special lecture at the university March 13 under the auspices of the Phi Chi Medical fraternity.

Memorial Lectureship.—A memorial lectureship in honor of Arnold C. Surman, senior medical student killed at Post, Texas, in an airplane crash in the summer of 1946, has been established by the Alpha Kappa chapter of the Phi Beta Pi medical fraternity at the University of Texas Medical Branch, Galveston. The first lecture was given by Dr. George E. Burch, associate professor of medicine, Tulane University of Louisiana School of Medicine, New Orleans, March 4 on "Salt and Water Balance in Cardiac Conditions."

WISCONSIN

State Society Publishes Blue Book. — The 1947 Blue Book issue of the *Wisconsin Medical Journal* is off the press. Special feature of the book is the outline of the activities of the Wisconsin Veterans Medical Service Agency of the State Medical Society. Topics include procedures for service under the agency and its relation to the Veterans Administration and to the Wisconsin Department of Veteran Affairs. In addition, the laws of Wisconsin pertaining to the medical profession have been reviewed. Complimentary issues have been sent to all junior and senior medical students of both medical schools in Wisconsin.

Cancer Symposium.—The Medical Society of Milwaukee County will hold a cancer symposium April 10-11 at Marquette University School of Medicine auditorium beginning Monday at 8 p. m. Among the speakers will be Drs. Charles B. Huggins, professor of surgery (urology), University of Chicago Medical School, "Diagnosis and Treatment of Cancer of the Prostate"; Ursus V. Portmann, radiologist, Cleveland Clinic, Cleveland, "X-Rays and Cancer of the Breast"; Michael E. DeBakey, assistant professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, "Carcinoma of the Lung"; Stanley P. Reimann, professor of oncology, Hahnemann Medical College and Hospital of Philadelphia, "Philosophy of Cancer Research"; Grantley W. Taylor, instructor in surgery, Harvard Medical School, Boston, "Lymphatic Metastases of Cancer," and Owen H. Wangensteen, professor of general surgery, University of Minnesota Graduate School, Minneapolis-Rochester, "Carcinoma of the Stomach."

GENERAL

Pediatric Professors.—Dr. Franklin P. Gengenbach, Denver, has been made emeritus professor of pediatrics in the University of Colorado School of Medicine. He is succeeded by Dr. Harry H. Gordon, New York City. Dr. Edwards A. Park, Baltimore, has been made emeritus professor of pediatrics at Johns Hopkins University School of Medicine, Baltimore, and is succeeded by Dr. Francis F. Schwentker, formerly of Larchmont, N. Y.

Dr. Whitfield Heads Federation of State Boards.—At the recent conference of the Federation of State Medical Boards of the United States, held in Chicago, Dr. Richard N. Whitfield, Jackson, Miss., for twenty-three years director of vital statistics and assistant secretary, Mississippi State Board of Health, was elected president. Dr. Whitfield is a graduate of the University of Nashville, 1905, and has served more than thirty years in public health work in Mississippi.

Endocrinology Awards.—"The Clinical Use of Androgens in the Female" is the subject for the 1947 Schering Award competition among medical students in the United States and Canada. As in previous years, cash prizes of $50, $300 and $500 will be given for the best manuscripts received on this subject. Three judges prominent in endocrinology will select the winners. Dr. Norman L. Heminway, Somerville, N. J., head of the Schering medical service department, is chairman of the Schering Award Committee and in charge of the competition. This year's contest closes July 31.

American Board of Obstetrics and Gynecology.—The next oral examination and annual meeting of the American Board of Obstetrics and Gynecology will be held at the Hotel William Penn, Pittsburgh, June 1-7. The following examiners have been appointed to assist the directors of the board: Drs. William C. Danforth, Evanston, Ill.; John L. Parks, Washington, D. C.; Robert L. Faulkner, Cleveland; Samuel A. Cosgrove, Jersey City, N. J.; Lawrence M. Randall, Rochester, Minn.; Nicholson J. Eastman, Baltimore; Conrad G. Collins, New Orleans; William J. Dieckmann, Chicago; Clifford B. Lull, Philadelphia; Josiah R. Eisaman, Pittsburgh, and Herbert E. Schmitz, Chicago.

Physician and Dentist Legislators.—In the present 80th Congress there are eight physicians and two dentists, one more physician and one less dentist than in the 79th Congress. As a result of an inquiry it was learned that in thirty state legislatures there are fifty-three physicians and sixteen dentists, while eighteen states report no physicians or dentists in their legislatures. Eighteen states have but one physician, while nine have two physicians serving this year, and three have four, five and six respectively. The governor of Idaho, Dr. C. A. Robbins, Boise, is a physician, and the governor of Wyoming is a dentist, Dr. Lester C. Hunt. Twelve states have one or two dentist legislators. One legislator holds a degree of D.D.S. as well as that of M.D.

Interim Commission of World Health Organization Meets March 31.—World problems in public health will be reviewed and major technical advances studied when more than a hundred international leaders in medicine and public health meet in Geneva, Switzerland, March 31 for the third session of the World Health Organization Interim Commission. The Food and Agriculture Organization, the Social Affairs Department of the United Nations and the United Nations Educational, Scientific and Cultural Organization will send observers. Other agencies invited include the International Refugee Organization, the Provisional International Civil Aviation Organization, the International Children's Emergency Fund, the International Labor Organization and the United Nations Relief and Rehabilitation Administration. The Interim Commission is composed of eighteen member states: Australia, Brazil, Canada, China, Egypt, France, India, Liberia, Mexico, the Netherlands, Norway, Peru, the Ukrainian Soviet Socialist Republic, the Union of Soviet Socialist Republics, the United Kingdom, the United States of America, Venezuela and Yugoslavia. The $1,500,000 field service function transferred from the United Nations Relief and Rehabilitation Administration will be given final allocation by the Interim Commission. This program includes fellowships and lectureships and field missions in eleven countries which formerly received UNRRA health assistance. The program for the expert technical committees will be outlined and membership announced for committees on malaria, quarantine, biologic standardization, narcotics, pilgrimage clauses and yellow fever. Dr. H. van Zile Hyde, U. S. Public Health Service, and Howard Calderwood, U. S. State Department, will attend from the United States government. Dr. F. A. Calderone, director, Interim Commission headquarters office, will head a small group of specialists from the Interim Commission Secretariat who will attend the conference. United Nations observers will include Dr. Gustavo de Sa Lessa, chief of the Health Section of the Social Affairs Department, and Dr. J. M. Latsky of the Nutrition Section of the Food and Agriculture Organization.

Awards by Insurance Medical Research Fund.—The Life Insurance Medical Research Fund of New York has announced the award of more than $500,000 for research in the field of cardiovascular disease. The fund made forty-eight grants in aid of medical research, thirteen postgraduate research fellowships and one student research fellowship. Grants of more than $15,000 each were as follows:

Massachusetts General Hospital, Boston, for research by Drs. James C. White, Paul D. White and Fiorindo A. Simeone on hypertensive and peripheral vascular disease with special reference to the role of the autonomic system, including laboratory and clinical studies, $31,500.

Johns Hopkins University, Baltimore, for research by Dr. Francis F. Swentker on the pathogenesis and prevention of rheumatic fever, $23,625.

Harvard Medical School, Boston, for research by Dr. Lewis Dexter on the dynamics of the pulmonary circulation in disease and under conditions of rest and stress, $21,000.

Jefferson Medical College of Philadelphia for research by Dr. John H. Gibbon Jr. on the temporary artificial maintenance of the circulation, $21,000.

The Children's Hospital, Philadelphia, for research by Dr. T. F. McNair Scott on the role of hemolytic streptococci in the etiology of rheumatic fever (renewal), $19,950.

New York University for research by Dr. David P. Earle Jr. on the relationship between renal function and the volume and composition of body fluids, $18,900.

University of Minnesota Medical School, Minneapolis, for research by Dr. Maurice B. Visscher on induced hypertension (renewal), $18,900.

Emory University School of Medicine, Atlanta, for research by Drs. Daniel C. Elkin and James V. Warren on the nervous and vascular factors in myocardial ischemia and infarction, $16,800.

New York University for research by Dr. Colin M. MacLeod on the purification, properties and mode of action of streptolysin O and S and fibrinolysin and their relation to rheumatic fever (renewal), $16,065.

University of California Medical School, Berkeley-San Francisco, for research by Drs. Israel L. Chaikoff and William J. Kerr on some fundamental factors in the aging process, $15,750.

University of California for research by David M. Greenberg, Ph.D., on metabolic changes in the kidneys and arteries associated with the development of hypertension and arteriosclerosis, $15,750.

Annual Meeting of American College of Physicians.—The twenty-eighth annual meeting of the American College of Physicians will be held in Chicago April 28-May 2 under the presidency of Dr. David P. Barr, professor of medicine, Cornell University Medical College, New York. General headquarters will be at the Palmer House; other official hotels include the Bismarck, Congress; Chicagoan, Morrison, Sherman and the Stevens. The general sessions will be addressed by numerous speakers on a variety of subjects, of which only a few can be mentioned here on account of lack of space. The following physicians will speak by invitation:

Walsh McDermott, New York, Streptomycin in the Treatment of Tuberculosis.
Harry Eagle, Baltimore, Pharmacologic Properties of Penicillin and Their Bearing on Therapeutic Activity.
Frank L. Horsfall Jr., Seattle, Primary Atypical Pneumonia.
Fuller Albright, Boston, Adrenal Cortical Syndromes and Their Diagnoses.
Abner McGehee Harvey, Baltimore, Use of Drugs in the Treatment of Diseases of the Muscles.
Donald D. Van Slyke, New York, Effect of Shock on the Function of the Kidneys.
Ephraim Shorr, New York, Humoral Factors of Hepatorenal Origin in Shock.
Arthur C. Corcoran, Cleveland, Functional Pathology of Renal Disease.
J. Erik Jorpes, Stockholm, Sweden, Origin and Physiology of Heparin.
J. Garrett Allen, Chicago, A New Concept and Treatment of Purpura Hemorrhagica.
Isadore Snapper, New York, Chemotherapy of Multiple Myeloma.
Frederic A. Gibbs, Chicago, Management of Grand Mal and Petit Mal.
James L. Holland, Washington, D. C., Human Factors in High Performance Aircraft.

Clinics will be held at various local hospitals. The series of panel discussions on topics of practical value will be under the chairmanship of distinguished authorities. A program of entertainment for the ladies has been arranged. The headquarters of the technical exhibitors will be at the Congress Hotel. Those desiring to make hotel reservations should address the Housing Committee, American College of Physicians, % Chicago Convention Bureau, 33 North La Salle Street, Chicago 2. The complete program appears in the February *Annals of Internal Medicine.*

LATIN AMERICA

Sylvatic Plague Found in Peru.—Dr. Atilio Macchiavello of the Pan American Sanitary Bureau in Lima, Peru, reports that sylvatic plague has been found in highly concentrated form in the small animal population of a mountainous region on the frontier between Peru and Bolivia. Domestic rat species are completely absent from the area, but intense infection has been discovered in several species of ground squirrels. Nineteen human cases have been reported.

Special Society Elections.—New officers of the Sociedad Nacional de Cirugia of Cuba for the years 1947-1948 are Dr. Vicente Banet y Pina, Havana, president; Dr. José Lastra Campo, Havana, vice president; Dr. René Smith Leal, Havana, secretary; Dr. Luis Rodriguez Baz Alfonso, Havana, vice secretary; Dr. Antonio Rodriguez Diaz, treasurer, and Dr. Tomás R. Armstrong, Havana, vice treasurer.——New officers of the Sociedad Argentina de Pediatria for 1947 are Drs. Jose Maria Macera, president; Pascual R. Cervini, vice president, and Samuel Gonzalez Aguirre, general secretary. Other officers include Drs. Alfonso A. Bonduel, Alfredo Segers, Juan P. Garrahan, Carlos Ruiz, Alfredo Casaubon, Fernando Schweizer and Raul Cibils Aguirre.

CORRECTIONS

Harry Hoxsey.—In the editorial entitled "Hoxsey—Cancer Charlatan" (THE JOURNAL, March 15, p. 774) the statement was made that Norman Baker had died. It appears now that he is still alive and that he recently attempted, with a brother and a Davenport, Iowa, attorney, to establish a research organization (one of its purposes being the collection of money) to study a new method of food preservation. The secretary of state in Iowa refused the petition.

Book Review: Horney's "Are You Considering Psychoanalysis?"—The review of this book, published in THE JOURNAL, March 8, page 732, fails to include the Philadelphia Psychoanalytic Institute in the list of training institutions affiliated with the American Psychoanalytic Association. The Philadelphia Psychoanalytic Institute, we are informed by Dr. Robert S. Bookhammer, was organized in 1940 and is a recognized and approved institute for training in psychoanalysis.

Marriages

WILLIAM THEODORE VAN HUYSEN, Weston, Mass., to Miss Yvette Wheeler Harrington of New Haven, Conn., Dec. 6, 1946.

FRANKLIN J. MASCIA, Newark, N. J., to Miss Genevieve Helen Savarese of Jamaica Estates, N. Y., Dec. 21, 1946.

JEROME OTIS WILLIAMS, Nashville, Tenn., to Dr. Marguerite Elizabeth Lazenby of Statesville, N. C., Dec. 18, 1946.

JAMES WHITE MERRITT JR., Gainesville, Ga., to Miss Jeanne Barry MacConnell of Punta Gorda, Fla., Dec. 8, 1946.

MARY ELIZABETH MORRIS to Mr. John T. Nansen, both of St. Louis, at Fort Leavenworth, Kan., May 21, 1946.

FRANZ STEFAN STEINITZ to Miss Jeanne Ann Sonnenschein, both of Chicago, in Glencoe, Ill., Dec. 15, 1946.

FLOYD STERLING ROGERS JR., Washington, D. C., to Mrs. Ann Meem McLean in Baltimore January 18.

CHARLOTTE LOUISE MELLER, Minneapolis, to Mr. Charles E. Biddle of Honolulu, T. H., Nov. 30, 1946.

HARRY MICHAEL SIEGEL, Chicago, to Miss Nita Alice Eisenberg of Winnetka, Ill., Dec. 22, 1946.

SHIRAS M. JARVIS, Eureka, Calif., to Miss Christiane Lamoreau of San Francisco, Dec. 21, 1946.

JAMES ALECK KELLEY to Miss Mary Kent Seignious, both of Kingstree, S. C., in December 1946.

MONROE A. ROSENBLOOM to Mrs. Arlene Weisberg Franklin, both of Syracuse, N. Y., Nov. 22, 1946.

ARTHUR WEINBERG, Far Rockaway, N. Y., to Miss Gloria Balmuth of Belle Harbor Oct. 6, 1946.

JAMES W. RIGGS to Miss Mary Elizabeth Adams, both of LaFollette, Tenn., January 8.

GLEN COILE SHULTS to Miss Love Gray, both of Newport, Tenn., Dec. 20, 1946.

IRVING A. KATZ to Miss Helen Louise Klein, both of Chicago, January 26.

Deaths

Khleber Heberden Beall ⊕ Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1901; Johns Hopkins University School of Medicine, Baltimore, 1905; past president of the Tarrant County Medical Society; since 1923 treasurer and formerly vice president of the State Medical Association of Texas; past president of the Texas State Heart Association; served during World War I; during World War II was a member of the district appeal board for Selective Service; chief of staff of the W. I. Cook Memorial Hospital; first medical director of the Fort Worth Children's Hospital; vice president and member of the board and medical director of the State Reserve Life Insurance Company, director of the Fort Worth National Bank and member of the city school board; died Nov. 21, 1946, aged 68, of myocardial infarction.

John Bell Shoun ⊕ Elizabethton, Tenn.; Medical Department of Grant University, Chattanooga, Tenn., 1908; state representative from Johnson and Carter counties; for many years chairman of the Carter County Congressional Committee and member of the First District Judicial Committee; chairman of the Carter County Health Department and the Infantile Paralysis Committee; member of the Veterans of Foreign Wars, Southern Medical Association, Southern Railway Surgeons and the Tri-County Medical Society; served in France during World War I and later with the Army of Occupation in Germany; at one time sheriff of Johnson County; for many years owner of the Shoun Hospital and chief medical adviser of the North American Rayon Corporation; died January 14, aged 72, of coronary thrombosis.

John William Preston ⊕ Roanoke, Va.; born in Glade Hill, Va., Dec. 13, 1867; College of Physicians and Surgeons, Baltimore 1893; secretary of the Virginia State Board of Medical Examiners; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; member of the House of Delegates of the American Medical Association in 1927, 1928, 1929, 1930 and 1931; past president of the Medical Society of Virginia; member of the board of directors and formerly member and chief of staff, Roanoke Hospital; served on the staff of the Jefferson Hospital; chairman of medical advisory board number 31 and a member of the induction board in World wars I and II; died January 1, aged 79, of cerebral hemorrhage.

George Henry Stone, Norwalk, Conn.; Medical School of Maine, Portland, 1908; member of the American Medical Association, American Hospital Association and the Massachusetts Medical Society; past president of the New England Hospital Association and formerly director of the Bangor (Maine) Anti-Tuberculosis Association; served during World War I; at one time superintendent of the Eastern Maine General Hospital in Bangor and the Memorial Hospital in Worcester, Mass.; formerly assistant superintendent of the Peter Bent Brigham Hospital in Boston, where he had been executive assistant at the Boston City Hospital; died in New Orleans January 4, aged 64, of fracture of the skull.

James Orville MacDonald ⊕ New York; M.B., Queen's University Faculty of Medicine, Kingston, Ont., 1916 and M.D. in 1917; specialist certified by the American Board of Otolaryngology; associate clinical professor of otolaryngology at the New York Post-Graduate Medical School and Hospital, Columbia University, serving as attending otolaryngologist to hospital and dispensary; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; a lieutenant commander in the medical corps of the U. S. Naval Reserve during World War II; died in Savannah, Ga., January 13, aged 54, of cerebral hemorrhage.

Albert Ernest Rector ⊕ Appleton, Wis.; Rush Medical College, Chicago, 1897; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the State Medical Society of Wisconsin and the Outagamie County Medical Society; member of the state board of health; affiliated with St. Elizabeth Hospital, where he was a member of the executive staff since 1942; died January 13, aged 73, of coronary thrombosis.

James W. Craig, Circle Mont.; Western University Faculty of Medicine, London, Ont., Canada, 1901; member of the American Medical Association and the Southeastern Montana Medical Association; past president of the Montana Public Health Association; at one time health officer of Kearney County in Nebraska; county health officer of McCone County; formerly state senator; at one time associated with the Indian Service; medical director of the McCone County Hospital; died in the Northern Pacific Hospital, Glendive, Dec. 28, 1946, aged 69.

John Steel Anderson ⊕ Greensburg, Pa.; University of Pittsburgh School of Medicine, 1913; past president of the Westmoreland County Medical Society; member of the Pittsburgh Obstetrical and Gynecological Society; served during World War I; on the staff of the Westmoreland Hospital; died Dec. 22, 1946, aged 60, of coronary occlusion.

William John Berger, De Soto, Kan.; University of Minnesota Medical School, Minneapolis, 1943; interned at the City of Detroit Receiving Hospital in Detroit; served during World War II; died in the Kansas City (Mo.) General Hospital Dec. 27, 1946, aged 30, of coronary thrombosis.

Tony Christensen Brown, Kansas City, Mo.; Chicago College of Medicine and Surgery, 1907; died in the Trinity Lutheran Hospital Dec. 27, 1946, aged 73, of cerebral sclerosis.

Charles Wesley Burgwin, Guys Mills, Pa.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; died in the Spencer Hospital, Meadville, Dec. 25, 1946, aged 73, of carcinoma.

Bruce Clark, Hiwassee, Va.; College of Physicians and Surgeons, Baltimore, 1891; died Dec. 19, 1946, aged 80, of tuberculosis.

Clyde C. Collom, Mart, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; member of the American Medical Association; past president of the McLennan County Medical Society; affiliated with the Provident and Hillcrest hospitals in Waco; died in Santa Monica (Calif.) Hospital recently, aged 68, of hypertension and cerebral hemorrhage.

Louis Merriew Diemer, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1895; died Dec. 20, 1946, aged 72, of chronic glomerulonephritis.

Milton Goldberg ⊕ Los Angeles; University of Minnesota Medical School, Minneapolis, 1936; member of the American Psychiatric Association; interned at the Minneapolis General Hospital in Minneapolis and served a residency at the Boston Psychopathic Hospital; formerly a fellow in psychiatry at the Institute for Juvenile Research in Chicago and senior physician at the Manteno (Ill.) State Hospital; died Dec. 10, 1946, aged 35, of subarachnoid hemorrhage.

John William Hains, Kansas City, Kan.; University Medical College of Kansas City, 1903; died Dec. 9, 1946, aged 79, of pneumonia.

Richard Theodore Hamilton, Dallas, Texas; Howard University College of Medicine, Washington, D. C., 1893; died in Montgomery, Ala., Dec. 12, 1946, aged 77.

Alva Arling Heil, Milford, N. J.; Medico-Chirurgical College of Philadelphia, 1897; died Dec. 15, 1946, aged 73, of cerebral hemorrhage.

William George Jack, Caney, Kan.; Kansas City (Mo.) Medical College, 1900; formerly coroner of Chautauqua County; died in the Mercy Hospital, Independence, Dec. 20, 1946, aged 72, of tachycardia.

Anson Herbert Kendall, Jaffrey, N. H.; Boston University School of Medicine, 1933; member of the American Medical Association; interned at the Massachusetts Memorial Hospitals in Boston, where he served a residency; died Nov. 9, 1946, aged 48.

Junius L. Lambert, Brazil, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1902; member of the American Medical Association; served as city and county health officer; died January 2, aged 86, of cerebral thrombosis.

Winford Porter Larson, Minneapolis; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1904; member of the American Association of Pathologists and Bacteriologists and the Society of American Bacteriologists; professor of bacteriology and immunology at the University of Minnesota Medical School and the University of Minnesota Graduate School; died in the University Hospital January 1, aged 66, of subacute bacterial endocarditis.

Charles Dixon Smith Lovell, Lynn, Mass.; Bellevue Hospital Medical College, New York, 1892; formerly on the staff of the Union Hospital; died in the Lynn Hospital Dec. 27, 1946, aged 82, of strangulated left scrotal hernia.

Jesse G. McAfee, Dalton, Ga.; Atlanta Medical College, 1888; member of the American Medical Association; served as mayor of Dalton; chairman of the local Water, Light and Sinking Fund Commission; on the staff of the Hamilton Memorial Hospital; died Dec. 28, 1946, aged 83, of pneumonia.

Thomas J. McLauchlin, St. Matthews, S. C.; University of Georgia Medical Department, Augusta, 1889; died in Columbia Nov. 18, 1946, aged 82.

Frederic Hurst Maier, Philadelphia; Jefferson Medical College of Philadelphia, 1894; member of the American Medical Association; fellow of the American College of Surgeons; at one time on the faculty of his alma mater; past president of the Philadelphia County Medical Society; served on the staffs of Philadelphia General Hospital and St. Joseph's Hospital; died Nov. 1, 1946, aged 75, of circulatory collapse.

William Theodore Martin, *Albany,* Mo.; Rush Medical College, Chicago, 1897; member of the American Medical Association; died Dec. 24, 1946, aged 83, of heart disease.

Samuel Evans Massengill, Bristol, Tenn.; University of Nashville Medical Department, 1899; member of the American Medical Association; died Dec. 15, 1946, aged 75, of coronary thrombosis.

Robert Gilbert Moore, Hazlet, N. J.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1902; died in the Dr. E. C. Hazard Hospital, Long Branch, Dec. 17, 1946, aged 66, of coronary thrombosis.

Elijah Marion Moseley ⊕ Rusk, Texas; Barnes Medical College, St. Louis, 1900; for many years county health officer; died Dec. 31, 1946, aged 73, of cerebral hemorrhage.

Henry Albert Nigg, Merrill, Iowa; State University of Iowa College of Medicine, Iowa City, 1888; died in Council Bluffs Dec. 2, 1946, aged 83.

Louis Alfred Palmer, Savannah, Ga.; Northwestern University Medical School, Chicago, 1920; fellow of the American College of Surgeons; for twenty-eight years associated with the U. S. Public Health Service, in which he had risen to the position of senior surgeon; died at the Mayo Clinic, Rochester, Minn., Dec. 13, 1946, aged 54, of recurrent lymphoblastoma.

Flavius Ogburn Plunkett ⊕ Lynchburg, Va.; University College of Medicine, Richmond, 1911; member of the South Atlantic Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; past president of the Virginia Society of Obstetricians and Gynecologists; formerly vice president of the Medical Society of Virginia; served during World War I; affiliated with the Virginia Baptist Hospital, where he died Dec. 18, 1946, aged 60, of cerebral hemorrhage.

John Harvey Proctor, Milford, N. H.; Dartmouth Medical School, Hanover, 1901; died in Concord recently, aged 74.

Joseph Record ⊕ Beaumont, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1911; veteran of the Spanish-American War; on the staffs of Hotel Dieu and St. Therese hospitals; vice president of the First Federal Savings and Loan Association; died January 14, aged 70, of uremia.

Byrd Smith Rhea, Lebanon, Tenn.; Vanderbilt University School of Medicine, Nashville, 1901; died in Ormond, Fla., Dec. 23, 1946, aged 72.

Edwin Z. Ruth, Stouchsburg, Pa.; Jefferson Medical College of Philadelphia, 1909; member of the American Medical Association; affiliated with St. Joseph Hospital in Reading; died Dec. 19, 1946, aged 61, of coronary occlusion.

Joseph H. Saye, Sharon, S. C.; College of Physicians and Surgeons, Baltimore, 1885; honorary member of the South Carolina Medical Association; member of the American Medical Association; served as mayor of Sharon, member of the state house of representatives, school trustee and chairman of the York County Permanent Road Commission; president of the First National Bank; affiliated with the York County and St. Philip's Mercy hospitals; died Dec. 27, 1946, aged 84, of heart disease.

Philip H. Schoen ⊕ New Albany, Ind.; Kentucky School of Medicine, Louisville, 1898; for many years secretary of the Floyd County Medical Society; formerly treasurer of the school board; on the staff of St. Edward's Hospital; died January 20, aged 76, of arteriosclerotic heart disease.

Hugh Robert Schofield ⊕ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1901; died in Los Angeles January 12, aged 71.

Lieut. August P. Laudicina
M. C., A. U. S., 1914-1944

Walter B. Simpson, Jefferson City, Mo.; University of Louisville (Ky.) Medical Department, 1891; for many years mayor of Edina; died January 15, aged 78, of arteriosclerotic myocarditis.

William Ewing Sinclair, Orlando, Fla.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1914; member of the American Medical Association and the American Academy of Pediatrics; specialist certified by the American Board of Pediatrics; served with the Royal Canadian Army during World War I; affiliated with the Orange General Hospital; died Dec. 30, 1946, aged 55, of coronary thrombosis.

Henry Galen Snyder ⊕ Seneca, Kan.; Rush Medical College, Chicago, 1903; on the staff of the Seneca Hospital; served during World War I; died Dec. 21, 1946, aged 66, of coronary thrombosis.

Frederick Edward Sperry, Buffalo; University of Buffalo School of Medicine, 1910; member of the American Medical Association; served with the British Expeditionary Forces during World War I; examining physician and surgeon for the New York Central Railroad; on the staff of the Millard Fillmore Hospital, where he died Dec. 6, 1946, aged 60, of cerebral hemorrhage.

Eugene Aaron Spitz, Chicago; Northwestern University Medical School, Chicago, 1906; died Dec. 28, 1946, aged 64.

Joseph Augustus Stegmenn Jr., Cape May, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1912; died Dec. 14, 1946, aged 56, of pulmonary infarction and coronary sclerosis.

Emil Synovec, Pierce, Neb.; University of Nebraska College of Medicine, Omaha, 1943; interned at St. Elizabeths Hospital in Washington, D. C.; began active duty as a first lieutenant in the medical corps, Army of the United States, in January 1944; released from active duty in October 1946 with the rank of captain; died in Erick, Okla., January 7, aged 38, of heart disease.

Joseph Charles Thurman, Denver; Barnes Medical College, St. Louis, 1894; died Dec. 19, 1946, aged 79, of coronary thrombosis.

Lucius Newton Todd ⊕ Augusta, Ga.; University of Georgia Medical Department, Augusta, 1915; professor of tuberculosis at his alma mater; physician in charge of the Wilhenford Unit of the University Hospital; died Dec. 12, 1946, aged 56, of pulmonary tuberculosis.

Howard Pleas Wheeler, Georgetown, Texas; University of Texas School of Medicine, Galveston, 1932; member of the American Medical Association; served during World War II; died January 20, aged 37, in an automobile accident.

Frank A. Wiley, Earlville, Ill.; Rush Medical College, Chicago, 1888; served on the school board for many years and as member of the library board; member of the American Medical Association; died January 8, aged 80, of cerebral hemorrhage and pneumonia.

KILLED IN ACTION

August Peter Laudicina, St. Louis; St. Louis University School of Medicine, 1936; member of the American Medical Association; interned at St. Mary's Group of Hospitals in St. Louis and St. Louis County Hospital in Clayton, Mo.; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army in 1941; assigned to the defense of the Philippines, embarking for overseas duty on Nov. 1, 1941 and arriving in Manila Nov. 18, 1941; assigned to station hospital at Fort McKinley as chief of obstetric and gynecologic section; at outbreak of war was assigned to General Hospital number 1, doing major surgery; ordered into Bataan Dec. 24, 1941; recommended for promotion to captain before the surrender of Bataan; a prisoner of war of the Japanese; was drowned in the South China Sea Oct. 24, 1944, aged 30, when the ship on which he was being transported was sunk.

Antidotal Property of Filtrates of Actinomyces Griseus

At the latest meeting of the Academy of Sciences G. Ramon, C. Levaditi, R. Richou and Miss Henry reported the results of their research on the antidotal property of the filtrates of Actinomyces griseus (Waksman) as regards diphtheria and staphylococcic exotoxins. In a mixture of equal parts of this filtrate and of staphylococcic toxin (kept in an incubator at 37 C.) 200 hemolytic doses of the toxin are completely destroyed within six hours; as regards certain filtrates, the destruction of the staphylococcic toxin is complete after three hours. On guinea pigs they obtained the complete destruction of 50 fatal doses of diphtheria toxin mixed with 0.9 cc. of an Actinomyces griseus filtrate, the mixture having been kept at 37 C. for twenty-four hours with certain filtrates this result is obtained after ten hours. The antidotal property of the filtrates (from which streptomycin is derived) is more stable to heat than that of Penicillium notatum; it does not begin to diminish appreciably until after half an hour's heating at 75 C. and it is completely destroyed at 100 C. On the contrary, these filtrates exposed to a temperature of less than 37 C., at 18 C. or even 4 C. retain their antidotal power; the effect occurs more slowly but is complete; for instance, in the case of diphtheria toxin after forty-eight hours at a temperature of 4 C. The addition of 0.03 cc. of formaldehyde solution to 100 cc. of filtrates does not alter essentially the antidotal property. The addition of human serum to the filtrates lessens the antidotal action on the staphylococcic toxin without preventing it; on the contrary, the action of the same filtrates on diphtheria toxin, with an admixture of human serum, lessening it considerably, renders it even incomplete; after eight days the presence of toxin is still noted in the mixture of filtrates, toxin and serum. It is therefore necessary to conduct further research in order to extract from the filtrates the antidotal principle in a form as active and as pure as possible and also, by fractionating the serums in their various components, to study their influence on the isolated, pure antidotal principle

Titration of Streptomycin by the Quick Method of Janus Green

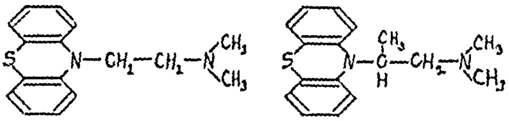
Mr. Prevot has presented to the Academy of Medicine the results of the quick titration of streptomycin. By using a culture of Clostridium butyricum he found that 0.31 cc. of a fresh culture of this anaerobe is inhibited by 3 micrograms of streptomycin (3 Waksman units); the result is obtained within two hours. By the same method the streptomycin sensitivity of other anaerobes has been ascertained: Clostridium welchi 130 units, Clostridium septicum 30 units, Clostridium histolyticum 36 units, Streptococcus putridus 110 units. Thus the pathogenic anaerobes appear less sensitive to streptomycin than to penicillin. As an improvement over the manual homogenization, electromagnetic homogenization is proposed.

Penicillin and Scarlet Fever

In the *Semaine des hôpitaux*, L. Justin-Besançon, H. P. Klotz and Luquet set forth their clinical observations on the effect of penicillin on the evolution of scarlet fever, which demonstrate the remarkable effectiveness on the eruption and the toxic manifestations. In 5 cases of malignant scarlet fever treated with doses averaging 200,000 units during three to four days, they saw that, under the influence of the treatment, temperature and pulse revert to the normal within two to three days; the eruption blanches rapidly; polypnea, adynamia, prostration, delirium and insomnia recede within twenty-four to forty-eight hours; oliguria ceases rapidly; only hypotension is not modified. They also verified the remarkable influence of penicillin in doses of 50,000 to 200,000 units during two to four days on the general condition and the scarlatinal glands in 5 cases of scarlet fever secondarily aggravated on about the fourth or fifth day and in 4 complicated cases (among which was 1 of scarlatinal rheumatism). The effect on the scarlatinal glands occurs quicker *than that produced by sulfonamides.* The authors have also found it necessary to maintain doses in the course of treatment in order to avoid being obliged to resort, in case of relapse, to higher doses than the former efficacious ones. In the *Bulletin médical* A. Fouet and J. Talbot confirm the remarkable effect of penicillin in 3 cases of malignant scarlet fever, 2 of which were particularly serious. One of them was treated with 2,350,000 units during fifteen days, the second with 1,650,000 units during seven days and the third, less serious, with 100,000 units; 3 of them were completely cured. The authors call special attention to the rapid action on the general condition and the complications of purely streptococcic origin.

Research on a New Series of Synthetic Antihistaminics

At a meeting on Dec. 17, 1946 of the Société médicale des hôpitaux de Paris Professor J. Hamburger and Drs. B. Halpern and C. DeBray presented the results of their pharmacodynamic and clinical experiences on a new series of synthetic antihistaminics. These new bodies derive from thiodiphenylamine; the structural formulas are:



Synthetic histamines 3015 and 3277.

These bodies have a much greater antihistaminic power than the former ones, Antergan and Neoantergan, and produce at the same time a more pronounced antagonistic action on the bronchoconstrictor and vascular effects. The antianaphylactic activity of 3277 on animals is from five to ten times superior to that of Antergan and Neoantergan.

The authors observed 6 cases of obstinate urticaria which for years resisted every form of treatment, including the former antihistaminics. They started with five doses of 0.05 Gm. taken at regular intervals during the day and after meals; on the following days three daily doses to 0.05 Gm. The posology therefore represents 1:3 and 1:4 of that of Antergan and Neoantergan. Toleration is excellent, save for a tendency to drowsiness, which has been noted by certain patients. No manifestation of digestive intolerance has been noticed even after a treatment of six weeks and more. From tweny to twenty-five minutes after absorption of the first cachet, pruritus disappears and within the following hour the eruption pales and recedes. In 2 cases the authors saw the Quincke's edema accompanying the urticaria disappear. The curative action persists as long as the patient absorbs the medication; in a number of cases twenty-four to forty-eight hours after the cessation of the treatment the sensations reappear. The exceptionally powerful experimental activity of these new synthetic antihistaminics calls for clinical experiments on a larger scale.

Miscellaneous

Professor Leriche has just been promoted to me
the Academy of Medicine; he is a professor at th
France and was already a member of the Academy

The Rockefeller Foundation has just
$350,000 (about 42 million francs) to th
Research.

DENMARK

(From a Special Correspondent)

Copenhagen, Feb. 7, 1947.

A New Domus Medica?

The headquarters in Copenhagen of the Danish Medical Association and the Danish Medical Society, known as Domus Medica, was smashed to smithereens by the Germans during their occupation of Denmark. This building was not just a center for medical activities; it had become a symbol of all that is best in Danish medicine. Hence the almost passionate determination of Danish doctors to raise it up again, if possible in an even worthier form. But the cost! In these times of upward shifting prices it is difficult to count the cost of a new building, and the estimate of three million kroner (to include furniture as well as buildings) must necessarily be tentative. The real estate and insurance might perhaps yield half a million kroner. But it is a far cry from half a million to three million; the funds required must, perhaps, be borrowed; in other words the coming generations must help to shoulder this burden. It has also been suggested that kr. 250 should be levied from each of 1,400 younger doctors and kr. 500 from each of 2,600 older doctors, so that the total would be kr. 1,650,000. According to another calculation the average income of Danish doctors is between 12,000 and kr. 13,000, and the average capital between 43,000 and kr. 44,000. The total income of Danish doctors would therefore be about 43 million kroner, and the total capital 144 million. A levy of two or three million kroner should not therefore bleed the Danish medical profession white. But this is only one aspect or solution of the problem, and it is not necessarily acceptable to the bulk of the medical profession.

Treatment of Syphilis and Gonorrhea with Penicillin

In a memorandum the Danish Ministry of Health advises the medical profession concerning the treatment of syphilis and gonorrhea with penicillin based on a statement, dated Nov. 7, 1946, by the Danish Dermatological Society. It is pointed out that the action of penicillin on syphilis being still uncertain, arsenic and bismuth should be preferred except when the disease is resistant to or the patient intolerant of them. Congenital syphilis in infants and syphilis contracted late in pregnancy should also be added to this list of exceptions. It is also recommended that the penicillin treatment of syphilis should be undertaken only by specialists. As syphilis and gonorrhea are often contracted at the same time, penicillin treatment of the latter may well mask the former. It is therefore recommended that every person who has recently acquired gonorrhea should be treated with sulfathiazole 8 to 10 Gm. daily for three days, after which some 30 to 40 per cent of the patients should be cured. The others may be given penicillin only on the observance of certain precautions and after the patient has been warned of the risk of masked syphilis. Penicillin should be given in four intramuscular injections at intervals of three hours, the dosage being 50,000 units. A single injection of 200,000 units is less certain in its effects.

The Distribution of Doctors in Denmark

At the end of 1944 there were 3,875 doctors in Denmark, whose population is 3,998,000. This corresponds to 1 doctor to every 1,031 inhabitants. But if account is taken only of the 1,800 doctors in general practice, the ratio is 1 doctor to 2,215 inhabitants. As many as 1,464 doctors in Denmark are attached to hospitals and similar institutions, and there are 754 doctors who have qualified as specialists. It is a sign of the times that less than half of all the doctors are now engaged in general practice, which only a short time ago absorbed the majority of the medical profession. Yet many are convinced that the intimate and personal contact between patient and private practitioner is worth more to the former than the mechanized and often highly technical treatment available in the most magnificently equipped modern hospitals.

When to Discharge Patients with Scarlet Fever

The chief medical officer of Copenhagen has addressed a memorandum to the general medical practitioners in his district on the time to discharge patients with scarlet fever. Under the penicillin treatment of scarlet fever as practiced in the Blegdam Fever Hospital the infectious stage of the disease is shortened to such an extent that patients can often be discharged only eight to ten days after admission. Swabs from the throats of such patients do not yield hemolytic streptococci unless there has been reinfection after discharge. Children can therefore be admitted to schools, hostels and the like as soon as they are discharged from hospital, and parents need not fear spread of the infection if and when desquamation is observed in children after their discharge.

International Society of Surgery to Meet in London

The twelfth congress of the International Society of Surgery is to be held in London September 14 to 20. The topics to be discussed, with the opening speakers, are the role of penicillin in surgical practice, Sir Alexander Fleming, F.R.S.; recent advances in arteriography and venography, Professor Don Santos, Lisbon; recent advances in vascular surgery, Professor René Leriche, Paris; surgical treatment of pulmonary stenosis, Professor Blalock, Baltimore; operative treatment of fractures, Professor Danis, Brussels; results of early operations in war wounds of the lungs, Dr. Basos Ansart, Barcelona; results of heparin surgery, Dr. Crafoord, Stockholm; role of vasodilatation in arterial disease, Dr. Diez, Buenos Aires; skin defects: their repair by flaps and free skin grafts, Professor T. Pomfret Kilner; recent progress in the treatment of burns, a Russian surgeon. Members of the society who wish to take part in these discussions should send their names to the secretary, Mr. H. W. S. Wright, F.R.C.S., 9 Weymouth Street, London, W. 1.

Are We Becoming Less Intelligent as a Result of Dysgenic Breeding?

That the less intelligent have larger families than the more intelligent is an old observation. The fact has recently been investigated and given numerical precision by the Eugenics Society, which has published a paper by Sir Cyril Burt on intelligence and fertility. The result of intelligence tests which measure the standard of mental ability show a negative correlation ($r = -0.20$) between the intelligence quotient of a child and the size of the family to which it belongs. Members of larger families have on the average lower test scores than those of smaller families. At a meeting of the Eugenics Society Burt said that his investigations seemed to indicate a loss of about 2 points I. Q. on the Binet scale in a generation. This meant that children at a given age would be about four months retarded as compared with their parents at the same age. If this rate of decline continued for fifty years the number of feebleminded would be doubled and the number of scholarship winners halved. However, in the discussion Professor L. S. Penrose said that differential fertility was not a recent phenomenon, and, if it had gone on for long unmodified, that would mean that the race was becoming less intelligent. But it seemed reasonable to suppose that there were restitution factors which tended to keep intelligence at the same level. Some investigators suggested that the first born in a family were likely to be the most intelligent, the level of intelligence falling as the family grew. That would mean that in an era of large families the general intelligence would fall; but when, as now, families tended to be smaller, the result would be to raise the level of intelligence. Thus this factor would act in the opposite direction to the alleged fall in intelligence due to a differential birth rate.

Correspondence

FATALITIES ASSOCIATED WITH ANALBIS SUPPOSITORIES

To the Editor:—This is a preliminary report on fatalities associated with the use of suppositories of a bismuth salt of heptadienecarboxylic acid (diallyl acetic acid), marketed as "Analbis" and manufactured and sold by Specific Pharmaceuticals, Inc., of New York City.

The drug has been used for the past ten years in various European countries, particularly Hungary and France, for the alleviation of symptoms in acute inflammations of the throat, and preoperatively in tonsillectomies. In October 1943 the manufacturer made application to the Federal Food and Drug Administration for permission to manufacture and sell Analbis suppositories. The drug was widely distributed throughout the United States. It was also sold in Canada, Mexico, Puerto Rico, Cuba, Brazil and China. It is not included in New and Nonofficial Remedies, the official publication of the Council on Pharmacy and Chemistry of the American Medical Association. Several articles have appeared indicating its effectiveness in throat infections:

Silber, Samuel: The Treatment of Tonsillitis, Pharyngitis and Gingivostomatitis with the Bismuth Salt of Heptadienecarboxylic Acid in Cocoa Butter Suppositories, *J. Pediat.* **23:** 59 (July) 1943.

Stovin, Joseph S.: Acute Tonsillitis: Treatment by Rectal Administration of a New Bismuth Compound, *Arch. Otolaryng.* **39:** 259 (March) 1944.

Silber, Samuel: Bismuth Suppositories (Analbis) in Throat Infections, *J. Pediat.* **25:** 244 (Sept.) 1944.

Stovin, Joseph S.: Preoperative and Postoperative Care in Tonsillectomy, *Eye, Ear, Nose & Throat Monthly* **24:** 239 (May) 1945.

Perez, Eduardo R.: Tonsilitis aguda: su tratamiento con supositorios rectales de bismuto (Analbis), *Bol. Asoc. med. de Puerto Rico* **37:** 300 (Aug.) 1945.

Pharmacologic studies have been directed mainly toward the toxicity of the bismuth moiety.

On March 9, 1947 the Bridgeport *Herald* reported that 2 children had died in Norwalk, Conn., late in December 1946 following the use of Analbis suppositories. This was the first notice that the New York City Health Department had that the drug might be toxic and might even cause death. The following steps were taken immediately by the health department:

1. An investigation was made of the manufacturer's plant located in New York City. The physicians' experience reports on the drug available in the manufacturer's files were scrutinized.
2. The drug was ordered embargoed at drug wholesalers, jobbers, retail pharmacies and hospitals in New York City.
3. The export certificates for this drug were rescinded and foreign governments notified of this action.
4. This action on the part of the health department and the reason for it were released to the press. Radio newscasters also helped bring these items to the attention of the public.
5. Case records of acute hepatitis in children reported to the health department were reexamined to see if any of them were associated with Analbis medication.
6. The medical examiner of New York City was requested to reexamine his records of deaths in children with disease of the liver to determine if any of these cases had had Analbis medication.
7. Telegrams were sent to city and state health officers asking whether they had any reports of illness or fatalities following the use of Analbis.

As a result of this action the health department acquired information that there had been at least 11 deaths, 6 of them in New York City, that were associated with the use of this drug. All the deaths occurred in children. There were 4 additional deaths reported in which the use of Analbis was suspected.

From the reported cases the following symptoms appear to be characteristic: vomiting, drowsiness and pain in the abdomen, especially in the right upper quadrant. In several instances there were convulsions. In all cases there was rapid progression to coma and death in two to five days following the first administration of the drug. At autopsy there was a decided swelling of the liver, with necrosis of the liver cells and evidence of exudation of fluid into other organs. There was no stomatitis or enterocolitis as is usual in bismuth poisoning. In 2 cases in which chemical analysis of the organs was made no bismuth was found. The following case history is illustrative:

A white girl aged 2 years became acutely ill. The temperature rose to 104 F. A physician was called, and he made a diagnosis of acute follicular tonsillitis. He prescribed Analbis suppositories, "children's size." The child was given one suppository that night and another the following morning. The temperature came down, and the child felt better. That night the child developed convulsions, and the physician was again called. There was no fever at this time. The physician took the child to the hospital at 2:45 a. m. of the third day. At the hospital the child had twitches of the mouth, left side of the body and extremities. Reflexes were unobtainable. The child was stuporous and reacted only to painful stimuli. She was given half an ampule of nikethamide and half an ampule of caffeine with sodium benzoate. Later she was given 25,000 units of penicillin and a retention enema of 5 grains (0.3 Gm.) of chloral hydrate. She was also given 1 cc. of adrenal cortex extract and an intramuscular injection of 2 Gm. of magnesium sulfate in a 25 per cent solution. She was kept in an oxygen tent throughout the hospital stay.

The child died at 6:50 a. m. of that day, thirty-six hours after the initial use of the suppository. At postmortem the liver was found to be enlarged and edematous, and there was necrosis of liver cells. Toxicologic examination of the organ did not disclose any bismuth.

The Analbis suppositories were made in two strengths: one for children, colored white, containing 67.5 mg. of the drug, and the other for adults, colored orange, containing double this amount. The two types of suppositories were the same size, wrapped in plain metal foil and placed in unlabeled vials. Two vials were put in a small box which was labeled either "Children's Size" or "Adult Size." The pharmacist received his supply of the drug in these boxes. Once the suppositories were removed from the box there was no means of distinguishing them other than by color. This color was not discernible through the foil. There was no label and, if one was not familiar with the significance of the color, confusion regarding dosage could readily occur. Since the adult suppositories contained twice the amount of drug that was present in the children's size, and since the dose advised for a very young child was one half of the children's suppository, there was a possibility of as much as fourfold overdosage. The professional sample box contained a "child" and an "adult" package. Interchange of the suppositories might have easily occurred. In several instances in which death occurred only one or two suppositories were given within a period of twenty-four hours. Whether the fatalities were due to intrinsic toxicity of the drug, to overdosage, to idiosyncrasy or to synergistic action with other drugs, such as the anesthesia given for tonsillectomy, has not been determined up to the present time. The New York City Department of Health is continuing its studies on the effects of the drug.

On February 12 the manufacturer voluntarily stopped the production and distribution of Analbis suppositories and requested wholesalers and jobbers to return any stocks they may have had on hand. Unfortunately, no notice of this action was sent to the New York City Department of Health nor was any other type of publicity given. Investigation by the department of health revealed that on March 11 the drug was still available *throughout the city.* From March 12 to March 20 the department seized over 4,000 packages of these suppositories in hospitals and drug establishments. Samples which were widely distributed to physicians have not yet been recalled by the manufacturer.

For many years there have been provisions in the Sanitary Code of the City of New York requiring the reporting of all cases of drug poisoning. Similar provisions exist in codes of other cities and states. If any untoward reaction following the administration of a drug is noted and reported at once to local health authorities a prompt investigation can be made and further harm prevented. The manufacturer of pharmaceutical preparations has the definite responsibility of stopping manufacture and notifying local health officials as soon as he becomes aware that unusual reactions follow the use of his product.

The exact mechanism by which death was produced following the administration of Analbis has not yet been determined. One thing, however, is certain. Hospitals, drug manufacturers, pharmacists and physicians all must recognize their responsibility to report without delay cases of drug poisoning. Once poisonings have been reported, stocks of the dangerous drugs can be impounded. It is only through prompt notification that health departments are enabled to use effectively their powers to prevent such tragedies as those here reported.

Israel Weinstein, M.D., New York.
Commissioner of Health.

COMPARISON OF ROENTGEN TECHNICS IN TUBERCULOSIS

To the Editor:—Although self analysis is a most laudable form of criticism, it can sometimes take such an extreme form that it only defeats its own purpose. The investigation to determine the relative diagnostic efficiency of the various roentgen modalities employed in mass x-ray surveys for tuberculosis case finding by Birkelo, Chamberlain, Phelps, Schools, Zacks and Yershulamy (The Journal, February 8) resulted in the comment that no one technic was superior to the others. In itself this conclusion might lead one to accept any one method of roentgen survey as efficient as another. An examination of the results, however, does not entirely bear this out, for it revealed an astonishingly wide variation in interpretation by various examiners and by the same examiners at various times. One interpreter found 47 cases positive for tuberculosis, while four of the interpreters agreed on only 17 cases. Twenty per cent of the films which were called positive by one reader were called negative by another. The same films reread by the same examiner at a different date showed a reduction of 7 per cent in positive cases, as read originally, but revealed an addition of 19 new cases which were not recognized before.

This variability of interpretation was not traceable to any particular technic of roentgenography. Hence one can only conclude that this lack of uniformity was due in great part if not in whole to the element of human equation. That this factor enters into the field of roentgen interpretation, as it does in every endeavor, goes without saying. That it need appear to the extent indicated in this study is most unlikely. My experience with such projects (a survey of 2,840 persons is being prepared for publication) does not run parallel with the mentioned study. In our survey, employing five qualified interpreters, there was less than a 2 per cent variation in readings.

The reading of mass survey films is quite different from individual x-ray interpretation. In the latter much time is spent on the detailed study of the structure and form of abnormal shadows in an attempt to come as closely as possible to an absolute diagnosis. In the former the element of time and the absence of individual case interest exacts from the examiner an impersonal response. If his threshold of acuity is high and he is overly alert, he will interpret any minor disconfiguration, such as a slight peribronchial thickening or increased vascular marking, as indicative of pathologic change. If his threshold is low and his faculties not acutely tuned to intercept the shadows that come quickly before him, he will overlook many borderline changes and consider the film negative. The variation in results between two such interpreters will be considerable.

Experience with mass film surveys teaches one that the receptive mechanism for viewing and interpreting chest film shadows must be at a fine level of equilibrium, undisturbed by outside influence, and ever cognizant of what the mind is looking for. For this purpose it is necessary to have before one a simple mental classification into which one can quickly tabulate the abnormal film. Under the most exact and time consuming interpretation an absolute diagnosis is often at best only a supposition. Why should one attempt an etiologic diagnosis in rapid fire miniature or substandard technic? The x-ray film, particularly in surveys, is only a screen in tuberculosis case finding. It can only pick out the normal from the abnormal. It is the important clinical follow-up investigation that must tag the positive carrier. Hence the interpreter should tabulate his findings as (1) a normal or negative chest, (2) pulmonary abnormality significant in character and suggestive of tuberculous disease, (3) pulmonary pathologic change suggestive of tuberculous disease but not significant in character (healed scars, calcified lesions and the like), (4) pulmonary disease significant in character but apparently nontuberculous and (5) nonpulmonary disease of the chest.

Mass chest x-ray surveys are valuable weapons in the fight against tuberculosis. Used judiciously as a screening method to reach every individual it will hasten the day when this disease will be a minor factor in morbidity and mortality statistics of the nation.

Maurice Kovnat, M.D., New York.

SENSITIVITY TO FURACIN

To the Editor:—The paper entitled "Use of 5-Nitro-2-Furaldehyde Semicarbazone in Dermatology" (The Journal, February 1) aroused great interest here, especially in view of our unfortunate first experience with Furacin Soluble Dressing.

The patient was a white man who had no known allergy and who had never exhibited any skin sensitivity. He had sustained a fracture of the calcaneus several months previously. An area of pressure necrosis about the medial malleolus had developed from the cast, and the resulting infected ulcer was extremely slow to heal, little improvement having been obtained from local penicillin. Furacin dressings had finally been used, and a clean granulating base, suitable for grafting, had developed in ten days. The pinch grafts yielded approximately a 50 per cent take, Furacin having been used on all dressings subsequent to grafting.

At this point, in September 1946, the patient was consigned to care at this activity with the recommendation that Furacin dressings be continued. During the sixth week from the onset of the Furacin therapy, when a very small area remained to be epithelized, a slight erythema was noted at the daily dressing. By the following day the entire area developed an angry erythema and was covered with small vesicles. The donor site on the opposite thigh, which had been dressed with Furacin, became erythematous and developed a few vesicles also. In addition there was a generalized pruritus and urticaria, and the patient experienced headache and nausea. Only moist boric acid dressings were then used, but the grafts and surrounding epithelized tissue were lost completely, so that the resulting ulcerated area was approximately the size of the ulcer which had existed prior to the use of Furacin. After a prolonged period of conservative therapy this area finally epithelized.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act: Evidence; Right to Ignore Medical Theories.—The petitioner suffered a loss of vision after spending a day spreading hot tar over a large parking area. The tar gave off a considerable quantity of smoke and fumes. Subsequent examinations revealed a diseased tooth, and a culture of the pus of the tooth disclosed a Streptococcus viridans infection. The Workmen's Compensation Bureau held that the eye condition, uveitis, was caused by the working conditions, not the infection, and the employer accordingly appealed to the Supreme Court of New Jersey.

In awarding compensation, the deputy commissioner said "The main controversy in this matter as presented to me seems to be medical, and I suppose if we handled this case from the medical angle we never could get a decision . . . we don't try compensation cases on medical theories but on legal ones, because it is the legal principles that have to be applied to a resolution of the case. . . ." It is quite inaccurate, said the Supreme Court, to state that compensation cases are not tried on medical theories. Many cases are of necessity tried on medical theories because the facts do not lend themselves to demonstration. There is no legal theory which permits a tribunal to disregard the medical theories advanced by one side or the other.

One physician definitely stated that uveitis is always due to a constitutional cause and another conceded that the cause is "usually constitutional." Dr. Conrad Berens in his treatise on "The Eye and Its Disease" states that infected teeth are commonly believed to be responsible for focal reactions of the eye.

In the light of such medical testimony produced before the compensation bureau, and in view of the opinions of the medical text writers, the Supreme Court concluded that the hypothesis that the loss of vision was caused by the conditions of petitioner's employment was less probable than the hypothesis that it was due to uveitis brought on by the Streptococcus viridans infection. Since the petitioner did not sustain the burden of proof, the court therefore concluded that the award in his favor was erroneous. Accordingly the award had judgment in favor of the petitioner was reversed.—*Thackston v. Landsdell Co., 49 A (2d) 140 (New Jersey, 1946).*

Workmen's Compensation Act: Advice of Physician as "Good Cause" for Delay in Filing Claim.—The plaintiff filed a claim for compensation based on an accidental injury received in the course of his employment with the Houston Shipbuilding Corporation. From a judgment denying relief, the plaintiff appealed to the court of civil appeals of Texas, Galveston.

In November 1942 the plaintiff accidentally fell into a manhole and was treated for minor injuries at the "company hospital." He filed no claim for compensation at that time, however, and continued working until March 1944. In May 1944 he filed a claim for compensation benefits. The sole issue presented on appeal was whether or not there was sufficient evidence to support a finding that the plaintiff had "good cause" for failing to file his claim within the six month period required by the workmen's compensation act. The ground relied on by the plaintiff as justifying his eighteen month delay was that he had been told by physicians on whom he relied that his condition was due to rheumatism and heart trouble caused by syphilis and that not until shortly before he filed his claim was he definitely advised that his condition was due to the injuries received by him on Nov. 12, 1942. He alleged that he had relied on this advice, that but for such reliance he would have taken steps to learn, and would in all probability have learned much sooner, that his disability was caused by the injuries received in said fall and that he would then have filed his claim with the Industrial Accident Board without delay.

It has been held a number of times by our courts, said the court of appeals, that the advice of a physician to the effect that injuries are not of a serious nature but are temporary and trivial is sufficient to show good cause for the delay in filing a claim where it is shown that the claimant believed and relied on the statements made by the physician. The plaintiff testified that in February 1944 he was told that he had a heart condition probably due to the accidental injuries he had received in November 1942 but that he was later advised by a number of physicians employed by the shipbuilding company and its insurer that the discomfort and shortness of breath from which he was suffering were due to rheumatism rather than to his accidental injuries. Dr. Horace Feagan, who was employed by the employers' insurer and who treated him for several months in the early part of 1943, told him that the injuries had nothing to do with the discomfort he was suffering and advised him to have his teeth extracted. It required more than a year to have his teeth extracted and to secure dentures, and his condition became worse instead of better. In the latter part of April 1944 he was examined at the Scott White Clinic in Temple, Texas, and was advised that his trouble was due to a heart condition caused by syphilis. In May 1944 he was definitely advised that his disability was due to the accident, and he then employed an attorney, who filed his claim for compensation with the Industrial Accident Board.

Under the aforementioned authorities, said the court, the jury was entitled to form its own conclusions as to whether the plaintiff relied on the advice given him by the physician with reference to his physical condition and as to whether a person of ordinary prudence under similar circumstances would have been influenced thereby in delaying the filing of his claim with the Industrial Accident Board. We think, concluded the court of appeals, that the trial court erred in finding as a matter of law that the plaintiff did not show good cause for delay in filing his claim with the board. Accordingly the judgment of the trial court denying the plaintiff relief was reversed.—*Martin v. Travelers Insurance Co., 196 S. W. (2d) 544 (Texas, 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Mar. 22, page 884.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part II only.* Various centers, April 21-22. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 131 Riverside Dr., New York 24.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Oral.* Philadelphia, June 5-7. Final date for filing application is April 1. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Orthopaedic Surgery: Part I. San Francisco, April 25-26. Part II. Chicago, January 1949. Final date for filing application is Oct. 15, 1947. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

American Board of Pediatrics: Effective May 1, application fee will be $125.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Robert H. Ivy, c/o Clerical Secretary, 4647 Pershing Ave., St. Louis 8.

American Board of Radiology: Atlantic City, June 4-8. Final date for filing application is April 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S. W., Rochester.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. G. J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Role of Dermal Nonatopic Sensitivity (Tuberculin-Type Sensitivity) in Contact Dermatitis. S. Epstein.—p. 438.
Principles and Practice of Aerosol Therapy of Lungs and Bronchi. H. A. Abramson.—p. 440.
Contact Testing of Buccal Mucous Membrane, with Special Reference to Penicillin. L. Goldman and J. Farrington.—p. 457.
*Bone Age Studies in Children to Establish Diagnosis of Hypothyroidism. L. O. Dutton.—p. 461.

Bone Age Studies and Hypothyroidism.—Since the determination of the basal metabolic rate in children is practically useless, Dutton thinks that by far the simplest, least expensive and least time consuming test for hypothyroidism in children is a determination of the bone age by x-ray. It is also the most reliable evidence of the existence of this condition. The hormones chiefly concerned in the control of osseous development and growth are thyroid hormone, sex hormone, growth hormone and the gonadotropic and thyrotropic fractions of the anterior lobe of the hypophysis. Prolonged disturbances in the elaboration of these hormones result in recognizable disturbances of epiphysial growth and development. In addition to bone age studies, blood cholesterol determinations may reveal hypercholesterolemia as a confirmatory diagnostic aid.

*Tuberculosis of Penis: Report of 5 New Cases, and Complete Review of Literature. E. L. Lewis.—p. 737.
Modified Ombredanne Operation for Repair of Penile Hypospadias. A. E. Goldstein.—p. 746.
Wartime Urology in Navy.—F. P. Twinem.—p. 757.

Arteriography in Renal Diagnosis.—Wagner presents a modified technic of abdominal arteriography, featuring use of a hand syringe for injection instead of the pressure apparatus. Advantages of the hand syringe method are its simplicity and greater protection against extravasation by allowing detection of change in resistance during injection. Visualization of the renal artery and its branches is best when the needle is introduced one vertebral level below the classic site. The difficulties and potential dangers of the procedure can be minimized by a competent team. One normal and two abnormal arteriograms are presented and interpreted.

Treatment with Ethinyl Estradiol in Carcinoma of Prostate.—McCrea analyzed 827 cases of prostatic carcinoma in 15 of which orchiectomy was combined with the administration of ethinyl estradiol instead of diethylstilbestrol. The side effects of ethinyl estradiol are apparently not as severe as those seen during the use of diethylstilbestrol. Combined therapy of castration and estrogens (ethinyl estradiol) produced subjective improvement in every instance. The dosage employed was 0.05 mg. daily for a period of thirty days, succeeded by a thirty day rest period. Such a routine may be continued indefinitely. *Transurethral resection was not done in a single instance after* combined therapy was instituted. Regression of the carcinomatous prostate occurred within thirty days after orchiectomy. Urinary difficulty or retention was controlled by an indwelling urethral catheter. It is believed that transurethral resection should not be done routinely but only in instances in which regression of the prostatic carcinoma does not occur.

Tuberculosis of Penis.—According to Lewis, tuberculosis of the penis is rare. Of 110 cases reported in the literature 72 were the result of ritual circumcision, leaving 38 cases from all other causes. The disease is regarded as primary when no other endogenous focus can be demonstrated, and as secondary if there are pulmonary and/or genitourinary foci. Five cases are reported from the Brady Urological Institute, of which 3 are primary and 2 secondary. A theory is reiterated which regards most secondary cases as the result of reinoculation through coitus.

In the latter part of April 1944 he was examined at the Scott White Clinic in Temple, Texas, and was advised that his trouble was due to a heart condition caused by syphilis. In May 1944 he was definitely advised that his disability was due to the accident, and he then employed an attorney, who filed his claim for compensation with the Industrial Accident Board.

Under the aforementioned authorities, said the court, the jury was entitled to form its own conclusions as to whether the plaintiff relied on the advice given him by the physician with reference to his physical condition and as to whether a person of ordinary prudence under similar circumstances would have been influenced thereby in delaying the filing of his claim with the Industrial Accident Board. We think, concluded the court of appeals, that the trial court erred in finding as a matter of law that the plaintiff did not show good cause for delay in filing his claim with the board. Accordingly the judgment of the trial court denying the plaintiff relief was reversed.—*Martin v. Travelers Insurance Co., 196 S. W. (2d) 544 (Texas, 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Mar. 22, page 884.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part II only.* Various centers, April 21-22. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 131 Riverside Dr., New York 24.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Oral.* Philadelphia, June 5-7. Final date for filing application is April 1. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Orthopaedic Surgery: Part I. San Francisco, April 25-26. Part II. Chicago, January 1949. Final date for filing application is Oct. 15, 1947. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

American Board of Pediatrics: Effective May 1, application fee will be $125.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Robert H. Ivy, *c/o* Clerical Secretary, 4647 Pershing Ave., St. Louis 8.

American Board of Radiology: Atlantic City, June 4-8. Final date for filing application is April 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S. W., Rochester.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. G. J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Some Properties of Antigens and Antibodies. S. B. Hooker.—p. 425.
Role of Dermal Nonatopic Sensitivity (Tuberculin-Type Sensitivity) in Contact Dermatitis. S. Epstein.—p. 438.
Principles and Practice of Aerosol Therapy of Lungs and Bronchi. H. A. Abramson.—p. 440.
Contact Testing of Buccal Mucous Membrane, with Special Reference to Penicillin. L. Goldman and J. Farrington.—p. 457.
*Bone Age Studies in Children to Establish Diagnosis of Hypothyroidism. L. O. Dutton.—p. 461.

Bone Age Studies and Hypothyroidism.—Since the determination of the basal metabolic rate in children is practically useless, Dutton thinks that by far the simplest, least expensive and least time consuming test for hypothyroidism in children is a determination of the bone age by x-ray. It is also the most reliable evidence of the existence of this condition. The hormones chiefly concerned in the control of osseous development and growth are thyroid hormone, sex hormone, growth hormone and the gonadotropic and thyrotropic fractions of the anterior lobe of the hypophysis. Prolonged disturbances in the elaboration of these hormones result in recognizable disturbances of epiphysial growth and development. In addition to bone age studies, blood cholesterol determinations may reveal hypercholesterolemia as a confirmatory diagnostic aid.

Modified Ombredanne Operation for Repair of Penile Hypospadias. A. E. Goldstein.—p. 746.
Wartime Urology in Navy.—F. P. Twinem.—p. 757.

Arteriography in Renal Diagnosis.—Wagner presents a modified technic of abdominal arteriography, featuring use of a hand syringe for injection instead of the pressure apparatus. Advantages of the hand syringe method are its simplicity and greater protection against extravasation by allowing detection of change in resistance during injection. Visualization of the renal artery and its branches is best when the needle is introduced one vertebral level below the classic site. The difficulties and potential dangers of the procedure can be minimized by a competent team. One normal and two abnormal arteriograms are presented and interpreted.

Treatment with Ethinyl Estradiol in Carcinoma of Prostate.—McCrea analyzed 827 cases of prostatic carcinoma in 15 of which orchiectomy was combined with the administration of ethinyl estradiol instead of diethylstilbestrol. The side effects of ethinyl estradiol are apparently not as severe as those seen during the use of diethylstilbestrol. Combined therapy of castration and estrogens (ethinyl estradiol) produced subjective improvement in every instance. The dosage employed was 0.05 mg. daily for a period of thirty days, succeeded by a thirty day rest period. Such a routine may be continued indefinitely. Transurethral resection was not done in a single instance after combined therapy was instituted. Regression of the carcinomatous prostate occurred within thirty days after orchiectomy. Urinary difficulty or retention was controlled by an indwelling urethral catheter. It is believed that transurethral resection should not be done routinely but only in instances in which regression of the prostatic carcinoma does not occur.

Tuberculosis of Penis.—According to Lewis, tuberculosis of the penis is rare. Of 110 cases reported in the literature 72 were the result of ritual circumcision, leaving 38 cases from all other causes. The disease is regarded as primary when no other endogenous focus can be demonstrated, and as secondary if there are pulmonary and/or genitourinary foci. Five cases are reported from the Brady Urological Institute, of which 3 are primary and 2 secondary. A theory is reiterated which regards most secondary cases as the result of reinoculation through coitus.

Physiology (concluded). H. E. Hoff.—p. 855.
Acute Coronary Thrombosis, with Cardiac Infarction.—p. 879.
Ectopic Pregnancy.—p. 881.

Trichinosis in Massachusetts.—Ober says that in the ten year period 1936 to 1945 a total of 287 cases of trichinosis were reported to the Massachusetts Department of Public Health, with death in 7 cases, a mortality of 2 per cent. Seventy of these cases were reviewed for epidemiologic, clinical and laboratory data and compared with the accepted clinical picture of the disease. The clinical findings most frequently noted were fever, malaise, orbital edema and muscle pains. Eosinophilia was the most constant laboratory finding but must not be considered diagnostic in itself. The control of trichinosis can be guaranteed only by the complete cooking of all pork and pork products.

Tropical Diseases in Veterans.—Sapero thinks that of the diseases usually termed "tropical" those of a major occurrence in men who served overseas, in order of frequency, were dysentery, malaria, infectious hepatitis and dengue. There is small likelihood, despite the high wartime prevalence of dysentery, that chronic disability will occur in large numbers of veterans or that there will be a significant spread of bacillary infections in civilian communities. The end of the once serious problem of malaria appears to be in sight. The vast majority of recurring malarial infections have expended themselves, but the situation still does not warrant a relaxation of control efforts. The large scale occurrence of infectious hepatitis during wartime may result in dissemination incident to the therapeutic use of blood and blood derivatives. Intensive measures have been undertaken to prevent the further occurrence of smallpox epidemics. Modern rapid civilian air travel presents a danger of smallpox introduction against which the surest countermeasure for civilian communities is comprehensive smallpox vaccination.

Recognition and Treatment of Venous Thrombosis (Phlebothrombosis and Thrombophlebitis), with Particular Reference to Prevention of Pulmonary Embolism. L. Kaplan.—p. 247.

Primary Sarcoma of Bone.—Shallow and Wagner present a critical analysis of 71 primary sarcomas of bone encountered in the Jefferson Medical College Hospital during the past twenty-five years. There were 35 osteogenic sarcomas, 11 chondrosarcomas, 3 fibrosarcomas, 1 liposarcoma, 1 adamantinoma, 8 Ewing's tumors and 12 multiple myelomas. The history of trauma in the majority of cases in the series suggests that it may assume some role in the genesis of these tumors. Arteriography may aid in differentiation between benign and malignant tumors but is not infallible. Biopsy, also not infallible, is the most reliable method of reaching a conclusion and is most safely performed in lesions of the extremities by frozen section examination of tissue removed by the double tourniquet technic. Since metastasis probably occurs early, prompt radical surgery offers the best chance of cure. Roentgen therapy and chemotherapy with lead, iron ascorbate and heptaldehyde are useful adjuncts. The prognosis is best in chondrosarcoma and fibrosarcoma, next best in osteogenic sarcoma and Ewing's tumor, and uniformly fatal in multiple myeloma.

*Significance of Chronic Urethritis in Women. E. Burns and A. J. Butt. —p. 352.
Vaginal Hysterectomy. O. S. Cofer.—p. 358.

Regional Enteritis Complicating Pregnancy.—Williams and Davis point out that the lesion which since Crohn's report in 1932 has been known as regional enteritis was previous to that time reported under the heading benign intestinal granuloma. Other terms applied to it include regional ileitis, ileojejunitis, segmental ileitis, Crohn's disease, nonspecific granuloma, phlegmonous enteritis and regional enteritis. Reviewing the *Cumulative Index Medicus* the authors found that heretofore there has been no report in the medical literature of regional enteritis complicating pregnancy. In this paper they present a case which became initially symptomatic at the period of viability and passed successively through the four classic stages of the disease. Normal spontaneous delivery occurred five weeks prematurely; the patient was treated successfully on the twenty-second postpartum day by primary resection of the diseased portion of bowel and subsequently made an uneventful recovery.

Chronic Urethritis in Women.—Burns and Butt define chronic urethritis as a condition in which pathologic inflammatory changes occur in the urethra and vesical trigone which appear granular on inspection and which produce many annoying urinary symptoms, chiefly irritation of the bladder and pain. The diagnosis is not difficult if complete urologic studies are made in suspected cases. The disease can be cured within six to eight weeks by irrigating the bladder, dilating the urethra with sounds and instilling solutions of silver nitrate into the posterior urethra. Predisposing factors may be responsible for recurrences. Consideration should be given to possible disease of the pelvic organs, especially the cervix, as well as to distant foci of infection. All such foci should be removed.

Bronchopulmonary Abnormalities. A. F. Foster-Carter.—p. 111.
*Tropical Eosinophilia or Pulmonary Acariasis. G. A. M. Hall.—p. 124.

Tropical Eosinophilia or Pulmonary Acariasis.—Hall presents the histories of 2 patients with distressing pulmonary symptoms and high eosinophil cell counts. One patient had never resided in the tropics. The working conditions of both patients prior to the development of their symptoms had included the passing of many hours in hot, damp and dusty storerooms. Arguments are presented in favor of a mite infestation as the cause of the "new disease entity" of Weingartner, and it is suggested that the condition merits the name of "pulmonary acariasis."

Atlas of Leprosy. D. C. Danielssena and C. W. Boeck.—p. 74.
Some Observations on Role of Allergy in Leprosy: Part II. Allergy and the Macular Series. T. F. Davey.—p. 75.
*Diasone in Treatment of Leprosy. E. Muir.—p. 87.
*Promin Therapy. L. H. Wharton.—p. 96.

Diasone in Leprosy.—Following a test of diasone in the treatment of 83 patients in the West Indies, which was previously described, Muir made a further test on 12 patients. The dosage is regulated till a maximum of 12 Gm. a week for three weeks in the month is reached. Beneficial results were obtained in all cases, though it is still too early to evaluate the final results.

Promin Therapy in Leprosy.—Wharton selected for promin therapy 7 young adults with advance lepromatous lesions, who were rapidly going downhill in spite of many years of the orthodox chaulmoogra oil treatment. The course consisted of 2 Gm. intravenously daily for the first six days and then one day's rest. The dose was gradually increased by 1 Gm. weekly until a maximum of 5 Gm. was reached. It was then continued at 5 Gm. daily throughout the year. At the end of every six weeks of treatment one week's rest was given. So great was the improvement at the end of six months that the other lepromatous patients demanded the drug. The 70 patients who have had six months' treatment with the drug have all shown remarkable improvement, especially as regards the healing of chronic ulcers. The author thinks that the beneficial results obtained by promin are due to the fact that the drug acts on the lepromatous tissue which is destroyed, with the formation of fibrous connective tissue. In the process leprous cells are destroyed, and the reduction in bacilli is due to their being unable to multiply. Promin is a safe drug to give over long periods.

Alcohol and Tuberculosis. M. Roch.—p. 790.
Tuberculosis of Genitals in Women. F. Chatillon.—p. 792.
Tuberculosis of Peritoneum. R. Montant.—p. 795.

Statistical Results of Screening Process.—The method of using 35 mm. films of fluoroscopic images for screening out persons with pulmonary disease has been employed widely in Switzerland. Surveys were made in 1945 and 1946 in the instruction centers for newly drafted soldiers and among civilians with a total of 48,137 persons examined. Diagnostic-etiologic clarification of the observations was required in 9.1 per cent of the examined persons in 1945; acute tuberculosis was demonstrated in 0.59 per cent and open tuberculosis in 0.13 per cent. Diagnostic-etiologic clarification was required in only 6.7 per cent of the examined persons in 1946, and the incidence of active and of open tuberculosis was correspondingly lower with 0.41 per cent and 0.06 per cent respectively. The screening process has so far been used only in highly civilized countries, and the reports from the United States, Great Britain, Canada and Switzerland correspond more or less with one another and reflect to some extent economic and social conditions. Kollbrunner also made a survey of an additional 6,571 persons who had survived in the concentration camp of Belsen-Bergen. Carriers of a primary complex should be found exclusively among these survivors if it would hold true that carriers of a primary complex are less susceptible, but in contrast to expectation a surprisingly small number of calcareous foci were found among the survivors, even less than among the newly drafted Swiss soldiers.

Plasmocytoma of Manubrium Sterni with Local Formation Amyloid. M. Dünner.—p. 1109.
Epilepsy During Pregnancy. L. Halpern.—p. 1111.

Thiouracil Derivatives for Hyperthyroidism.—Hadorn and Beer review observations on 18 patients with toxic diffuse goiter who were treated with methyl thiouracil. In 4 of them the substance was used for the preoperative treatment. Of 4 other patients 1 did not tolerate the drug, another one interrupted the treatment on her own initiative, a third one is still receiving the drug, and in a fourth one the basal metabolism decreased from plus 35 per cent to plus 3 per cent but the tachycardia remained uninfluenced by the drug as well as by strumectomy. Of the remaining 10 patients who were treated with methyl thiouracil 6 remained well and able to work after the drug was discontinued, but 4 again showed symptoms of toxic diffuse goiter after six months, but they subsided again after use of the drug was renewed. Mild swellings of the face, as symptoms of myxedema, were observed in some patients before the basal metabolism had decreased to zero. The authors conclude that methyl thiouracil represents the best drug against hyperthyroidism, although harmless secondary effects develop in about 10 per cent of the cases.

*Etiology of Contagious Hepatitis. O. Pendl.—p. 669.
Median Inguinal Hernia in Boy Aged 3. R. Jonas.—p. 673.

Impairment of Bone Marrow by Treatment with Arsphenamine.—Lachnit reports 2 cases of severe damage to the bone marrow as a result of arsphenamine treatment of syphilis. One patient was treated for only a comparatively short period, but all myeloid cell elements became greatly impaired. This patient died, whereas the second was cured by early resort to massive blood transfusions. The purely aplastic anemias have a more favorable prognosis than cases which also show involvement of the leukopoietic system. With regard to treatment the author stresses the importance of blood transfusion.

Etiology of Contagious Hepatitis.—Pendl experimented with duodenal juice from 131 patients in the jaundiced stage of hepatitis. Usually the duodenal juices of 7 patients were combined into 1 material. Feeding such material to young pigs resulted in microscopically demonstrable liver changes, which could be transmitted in 2 passages in the same species of animals. Contagious (epidemic) hepatitis is not regarded as identical with swine plague. Intraperitoneal inoculation of white mice with filtered duodenal juice produced hepatic changes like those in human hepatitis. The pathogenic substance passes filters that are impermeable for bacteria and it is regarded as a virus. Formations resembling virus bodies were seen in smears of duodenal juice with the aid of Giemsa's stain, in the dark field and in primulin-stained material by means of the luminescence microscope. Microscopic sections of the liver also revealed these bodies.

*Agranulocytosis and Penicillin. L. A. Faber Jr.—p. 1605.
*Intravenous Infusion in Acute Dehydration. J. R. Borst and A. N. F. Kooy.—p. 1609.
*Stretching of Sciatic Nerve Under Anesthesia in Treatment of Acute Rheumatic Sciatica. C. A. Cammaert.—p. 1616.
Empyema of Gallbladder in Young Child. T. Boesman.—p. 1619.
Agranulocytosis After Accidental Hemorrhage. J. J. van Luin.—p. 1621

Agranulocytosis and Penicillin.—Faber reports that a man aged 61 who was treated with sulfapyridine after an operation for hernia gradually developed an absolute agranulocytosis. In spite of treatment with pentnucleotide and blood transfusion the necrotic lesions of the mucous membranes progressed. Following treatment with penicillin and with fresh liver the patient improved, granulocytes making their first appearance after six days of treatment with penicillin.

Intravenous Infusion in Dehydration.—Borst and Kooy report the histories of 2 patients in whom severe circulatory disturbances and extreme dehydration resulted from a severe gastrointestinal upset of unknown origin. Intravenous drip infusion of isotonic solution of sodium chloride with 5 per cent dextrose proved to be of great value in overcoming the dehydration and the impairment of the circulation. If the dehydration is severe, large quantities may be infused in a relatively short time.

Stretching of Sciatic Nerve in Acute Rheumatic Sciatica.—Cammaert treated patients with acute rheumatic sciatica by bending the extended leg at the hip joint into abductions up to an angle of about 100 degrees. The bending is done by gradually increasing back and forth movements. This entire manipulation of stretching the sciatic nerve requires about ten minutes and is performed under deep ether anesthesia. The patients could walk after one or two days and were able to resume their work a week or two later.

Epidemic of Trichinosis.—Wird gives an account of an epidemic of trichinosis comprising 37 cases, none of which were fatal. The incubation period in the 7 cases in which it could be established was between fourteen and twenty-one days. Edema of the eyelids, the most characteristic early symptom, was present in all but 2 of the cases. Fever was recorded in all the cases. The blood picture showed leukocytosis with relative lymphopenia in the majority of cases, and all patients had eosinophilia varying between 6 and 72 per cent. Moderate and severe cases showed a higher degree of eosinophilia than did the mild cases. The skin test with trichina antigen gave a positive reaction in many cases but not in all. The precipitin test with living trichina larvae turned out positive in all cases. Sulfathiazole was tried but had no demonstrable effect. Some patients still had muscular discomfort from seven to eight months after onset.

Serologic and Skin Tests in Trichinosis.—Roth emphasizes that the direct demonstration of the parasites in stools, blood or muscles often fails in trichinosis. Intradermal skin and precipitin tests with an antigen prepared from dried, pulverized, extracted and filtrated larvae of Trichinella spiralis yielded good results in two outbreaks, but in some instances they failed and some false positive reactions were seen. The new microscopic precipitin test, however, with living larvae of Trichinella spiralis proved to be most sensitive and specific.

Thrombocytopenic Purpura Following Rubella.—Magnusson reports the histories of 2 girls aged 10 and 12. Both showed the ordinary clinical picture of rubella, but six and eight days after the onset both children started to bleed suddenly from the nose and mouth, and irregularly distributed ecchymoses made their appearance. The capillary resistance tests proved positive, and in both cases there was established a definite thrombocytopenia with resulting disturbance of the normal retraction of the blood clot and with prolongation of the bleeding time. The coagulation time was normal. Both patients recovered. The author discusses the conditions that give rise to this complication in rubella.

Pathologic Anatomy of Sudden Heart Death.—Munck analyzes observations made in the course of necropsies in 500 cases of sudden heart death. There were 411 men and 89 women. The sudden heart deaths occur in men most frequently in the age group between 40 and 60, in women at a somewhat higher age. Coronary sclerosis or its sequels was the cause of sudden heart death in 396 cases, infarction of the heart in 74 cases, rupture of the heart in 26 cases, chronic myocardial changes without simultaneous acute changes or coronary thrombosis in 142 cases, coronary thrombosis in 141 cases and syphilitic aortitis in 58 cases; in 9 cases congenital heart disease was the cause of death.

Immunotherapy in Diseases Caused by Staphylococci.—Pettersson shows that, although animals cannot be immunized with heat killed staphylococci, vaccines of staphylococci that have been detoxified by acetone and completely sterilized by formaldehyde will immunize animals against several times the lethal dose of staphylococci. This type of immunotherapy is applicable to human subjects with acne, furuncles, carbuncles and other lesions caused by staphylococci and possibly also to staphylococcic osteomyelitis.

Hygiea

Operative Technic in Incontinence of Urine. A. Ingelman-Sundberg.—p. 2297.

Complications in Chronic Familial Hemolytic Jaundice.—Aarseth observed a family in which several members presented hemolytic jaundice. According to most textbooks hemolytic jaundice is often accompanied by cranial defects or other malformations in the bony system, but this does not seem to be the case in the northern countries. Three complications are noted: cholelithiasis, arthritis urica and ulcus cruris. Hemolytic jaundice should be borne in mind when there are intractable ulcers of the leg, particularly in young persons without varices.

Book Notices

Plaster of Paris Technique in the Treatment of Fractures and Other Injuries. By T. B. Quigley, Lieutenant Colonel, Medical Corps, Army of the United States. Cloth. Price, $3.50. Pp. 107, with 103 illustrations. Macmillan Company, 60 5th Ave., New York 11, 1945.

This manual is designed to help the surgeon and his assistants acquire skill in applying plaster of paris casts in the treatment of traumatic conditions. Good technic is important if satisfactory results are to be obtained and serious complications avoided. The experience of war has emphasized the value of immobilization in the treatment of numerous types of injury. It is imperative that all concerned learn the correct technic for procedures in common usage. Of all methods of immobilization, the plaster of paris "cast" is, in general, unsurpassed for efficiency. It is cheap, durable and easily adapted to the individual case.

This book presents, by means of text and illustrations, proper technics for various types of casts useful to the practitioner. It discusses the types of material available and their preparation, preapplication fixation and padding, care of the patient while the cast is in place, and removal of casts in clean and in septic cases. It emphasizes the importance of constant watchfulness for signs and symptoms of complications resulting from tissue ischemia. Machine made bandages, although somewhat more expensive, are preferable. Fixation is easily achieved on any of the standard fracture or orthopedic tables but can be accomplished with little more special equipment that is found in the average household plus a moderate amount of ingenuity. The ideal cast has no other padding than stockinet, but it must be fashioned with the greatest care in molding over bony prominences, avoiding even the smallest folds, wrinkles and dents. "When in doubt, pad!" A pressure ulcer over a bony prominence can easily produce deformity and disability lasting much longer than the original injury for which the cast was applied. Adhesive tape should never be applied to the skin under a plaster cast. Some degree of infection is sure to occur in time, and some of the patients are more or less allergic to adhesive tape.

No circular bandage other than sheet wadding should be used under plaster of paris. Plaster bandages should not be "wrung out," but should be used "sloppy wet." Plaster bandages are laid and not pulled into place. Porosity of plaster of paris is one of its most valuable qualifications, and sealing with paint may result in maceration of the underlying skin. A number of serious complications can occur in a relatively brief period, all of which are the result of tissue ischemia. It is essential that every person concerned with the care of a plaster cast after its application be keenly aware of the danger signals. The symptoms are pain and numbness, and the signs are cyanosis, anesthesia and edema. Undiminished pain four hours after recovery from anesthesia should be regarded with grave suspicion. If it continues unabated for six hours, active measures for investigation and relief must immediately be instituted. Localized pain usually over bony prominences must always be investigated. "The patient is always right."

Ulcers can develop rapidly, especially in the aged and malnourished, and become painless in a few hours after the sensory nerve endings have been destroyed, only to be revealed later when the cast is removed. The first indication of ischemia or of pressure on a peripheral nerve may be tingling followed by numbness in the limb. The color of the extremity at the distal end of the cast should be the same as that of the uninjured limb when placed in the same position. It is therefore important that the sensation of the parts left uncovered by plaster (usually the fingers and toes) be carefully checked at frequent intervals during the first twenty-four hours after the application of the cast, especially if other signs or symptoms appear. To avoid complications, some surgeons, as a routine, split casts immediately after application. This is unnecessary and illogical. If any signs or symptoms appear, the surgeon who applied the cast should be informed at once.

Dr. William Darrach, who wrote a foreword to the book, says "Rarely have I seen so much horse sense and useful information tucked into such compact form."

The Personality of the Preschool Child: The Child's Search for His Self. By Werner Wolff, Professor of Psychology, Bard College, Annandale-on-Hudson, N. Y. Cloth. Price, $5. Pp. 341, with 118 illustrations. Grune & Stratton, 381 4th Ave., New York 16, 1946.

In 1943 Dr. Wolff published "The Expression of Personality: Experimental Depth Psychology," a book devoted to a study of the verbal, written and artistic productions of individuals as significant indexes of their motivations, symbolisms and personality. In the present volume Dr. Wolff applies his research methods to the preschool child, whom he proposes to evaluate by criteria that are intrinsically different from those applicable to the adult. In the first four chapters the author presents a brilliant and penetrating analysis of the intellectual, emotional and social growth of the child. He correctly points out that the usual tests for "average intelligence" are highly unreliable during the first three years of life, since the personality of the tester, the variability of circumstance and the highly labile sensitivities and emotional reactions of the child may prevent him from expressing his latent perceptive, integrative and esthetic talents. To measure these Dr. Wolff proposes a "rhythmic index" based on a geometric analysis of the child's drawings or other activities and designed to detect a sense of fitness and proportion. The author reaches two main conclusions: (1) that "it is almost as if the child and the adult live in two different planets" nearly devoid of intercommunication, and (2) that all of the child's activities revolve about a somewhat mystic "search for his self." To the specialist in this field some of Dr. Wolff's experiments and formulations will prove interesting and stimulating, although the experienced psychoanalyst will disagree with the author's insistent distinctions between the "depth psychology" of infant and adult. Both lay and professional readers, however, may find portions of the text obscure, the style dogmatic and repetitious, and the conclusions in some instances not discernibly supported by the data cited. Despite these recurrent defects, the work illuminates the imaginative and emotional universe of the preschool child and therefore merits a place in the library of the pediatrician, the child psychologist and the psychiatrist.

The Nature and Conditions of Learning. By Howard L. Kingsley, Professor of Educational Psychology, Boston University, Boston. Cloth. Price, $6. Pp. 579, with 30 illustrations. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1946.

This is a comprehensive textbook, written primarily for students of educational psychology. Learning is considered the "core of educational psychology." Laboratory studies are deemed the basic source of understanding of learning, and educational psychology must rely on such studies; classroom studies on learning are supplemental. The five major sections of the book consider the fundamental nature of learning, fundamental principles of learning, improvement, the learning curve and physical handicaps to learning, forms of learning and retention and transfer of learning. The author intentionally omits discussion of neurologic theories of learning and only most briefly outlines organic or bodily bases of learning, since he feels that the understanding of these is not the immediate concern of the teacher. Maturation, trial and error, repetition, motivation, conditioning and the principle of relationship and organization are the six fundamental principles of learning discussed. This is a carefully and clearly written book in which the author has diligently selected what he considers most significant in the laboratory studies on learning. It is no dry account, however, in which the laboratory is divorced from the living human being. The clinician who learns about learning primarily from human beings outside of laboratories will feel that discussions of development of emotional activity and of attitudes and ideals are thin; descriptive yet inadequate. An adequate consideration would involve consideration of mental processes and human relationships not readily amenable to study in laboratories. The tremendous gap that once existed between the so-called academic psychology of the classroom and laboratory and the apparently less scientific dynamic psychology of the clinical student of human behavior is rapidly narrowing. It seems that before long language will be found in which common denominators of the concepts formulated by the analytical clinician and by the educational psychologist can be stated.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ANTICOAGULANTS AND CORONARY THROMBOSIS

To the Editor:—Has heparin been used in the treatment of coronary thrombosis? How effective is the treatment? What is the procedure?

M.D., New York.

ANSWER.—Anticoagulants, in particular heparin and Dicumarol (3-3'-methylene-bis-[hydroxycoumarin]) have been used with the aim of preventing coronary thrombosis in coronary heart disease and in the treatment of acute coronary thrombosis with a view of preventing the spread of the thrombosis itself and the deposition of intracardiac thrombi, which can be a serious hazard in myocardial infarction as the result of the dispersion of peripheral emboli to the brain or elsewhere. There has been to date a varied but quite inadequate experience with such therapy, which should be considered as still in the experimental stage. As a matter of fact, a research has been begun to last a year or more, organized by Dr. Irving Wright, to be carried out in various parts of the country, to test the value of the use of Dicumarol in acute coronary thrombosis. It will be some time before properly controlled studies will have been completed. Before such a study has been completed, much caution should be exercised. Administration of the anticoagulants must be carefully followed daily to observe both the course of the disease itself and of the Dicumarol administration, with frequent testing of the prothrombin time and a quick use of antidote if difficulties should arise. Theoretically one may argue in favor of such therapy, and practically it may prove to be worth while; but in our present state of knowledge a decision cannot yet be made.

REPAIR OF HYPOSPADIAS

To the Editor:—Please discuss the use of a whole skin graft as a tube over an indwelling catheter for the formation of a urethra in cases of hypospadias. What liquid adhesive material is employed to make the skin graft stick to the indwelling catheter and thus avoid the use of sutures?

M.D., Canada.

ANSWER.—The use of a full thickness skin graft to repair the uretha in hypospadias has been employed with excellent results by Humby. The skin was taken from a hairless surface, preferably the inner side of the upper part of the arm, and glued to a catheter with benzol mastiche. The lower surface of the penis was then incised, the skin undermined and the septum between the corpora cavernosa split to half its depth. The graft with the catheter was then placed in position, the graft anastomosed to the urethra with fine silkworm gut sutures (which were later seen to pass via the urethra) and the overlying tissues and skin were sutured in place over the graft.

The technic is described in detail by Graham Humby in the *British Journal of Surgery* **29**:84 [July] 1941.

EFFECTS OF SULFONAMIDES ON FETUS

To the Editor:—Does sulfadiazine 1 Gm. four times a day for four to five days have any undesirable effects on the embryo in the first weeks of pregnancy?

Alvin C. Poweleit, M.D., Louisville, Ky.

ANSWER.—One case is recorded in which anemia in an infant was observed at birth after the mother had been treated with sulfanilamide in the eighth month of pregnancy. There was, however, little evidence to associate the anemia with the sulfonamide therapy. There was no evidence of fetal abnormality in 14 other similarly treated mothers. As far as the literature is concerned, then, there are no other instances in which there has been possible toxicity to the fetus. It is the general opinion that pregnancy should not be a contraindication to the administration of sulfonamides in full dosage when the mother has an illness that may be influenced favorably by sulfonamides. It might be unwise to give sulfadiazine for long periods either in small or in large doses. It is well known that the blood levels of the fetus and the mother rapidly reach equilibrium at the same level.

TOXOPLASMOSIS

To the Editor:—If a mother who has given birth to a child with toxoplasmosis (congenital type) becomes pregnant again, will she be likely to give birth to child with a similar condition?

Alvin C. Poweleit, M.D., Louisville, Ky.

ANSWER.—Toxoplasmic infection in infants and children has been reviewed by Sabin and has been discussed by several other students of the disease. In 15 cases reported, instances of toxoplasmosis have not occurred in siblings, and several infants were normal who were born previous or subsequent to the infant with toxoplasmosis. In other words, in the few cases that have been reported definite evidence is lacking that congenital toxoplasmosis will occur in repeated pregnancies. On the basis of the few cases that have been studied, it can be said that if a mother gives birth to a child with toxoplasmosis she may give birth to a perfectly normal infant in subsequent pregnancies.

ROUTINE VITAMIN K BEFORE DELIVERY

To the Editor:—For some years we have routinely administered Hykinone to all patients before delivery in order to diminish or prevent blood dyscrasias in newborn infants from low blood prothrombin levels. Is this medication of value? Patients are subjected to the inconvenience of hypodermic injections; the medication is expensive and nursing technic is complicated. Would it be wise to discontinue this routine practice? Maternity cases at this hospital average 2,500 a year.

Owen Jones Toland, M.D., Philadelphia.

ANSWER.—Estimates of the frequency of hemorrhagic disease of the newborn range from 0.1 to 0.7 per cent. It is not likely that every case is characterized by hypoprothrombinemia or likely to respond to administration of vitamin K. From this it would appear that more than two hundred times as many injections are being given as would be necessary if some test for K deficiency was used to identify the mothers who need the material. A critical study of the hospital records should be made in order to determine how many cases occurred before this routine was instituted and to estimate how many cases have been prevented since that time.

There is, of course, good reason to expect that K deficiency in the infant can be prevented by administering the vitamin ante partum to the mother, and water soluble preparations (of which Hykinone is one) are available to supplement the solutions in oil. But there are general objections to the indiscriminate parenteral administration of medicaments of any sort.

ALTERATION OF INTESTINAL FLORA

To the Editor:—What is the correct procedure to change the flora of the intestinal tract? Is the administration of 100 billion Lactobacillus acidophilus organisms daily and 100 Gm. of lactose or dextrin daily proper therapy?

M.D., Illinois.

ANSWER.—The plan of therapy outlined in the query should alter the intestinal flora. The coliform flora, normally containing a predominence of Escherichia coli, Streptococcus fecalis, L. acidophilus and Clostridium welchi, can be altered to one in which L. acidophilus and the closely related Lactobacillus bifidus grow to the exclusion of almost all other types of bacteria. The change can be accomplished by feeding very large amounts of lactose or dextrin and/or by feeding 100 billion L. acidophilus organisms daily. Rettger recommends drinking 1 quart (liter) of high quality acidophilus milk daily and a general diet with small amounts of meat and liberal amounts of foodstuffs, vegetables and milk. The Council on Pharmacy and Chemistry (New and Nonofficial Remedies 1934, p. 250) has stated that acidophilus milk should contain not less than 200 million viable bacilli per cubic centimeter on the day of manufacture and not less than 100 million per cubic centimeter on the expiration date. However, use of milks containing 400 to 500 million viable bacilli per cubic centimeter at time of delivery is recommended by Rettger. The acidophilus milk therapy should be applied faithfully over long periods (eight to twelve weeks and longer in some instances) and possibly repeated after a "rest period" of four to six weeks. The dietary phase of therapy should be adhered to continuously even after the bacterial therapy has ceased. It is best that alcohol be interdicted.

The therapeutic value of such alterations in the intestinal flora is highly questionable.

PSYCHIATRIC SENSE AND NONSENSE

C. C. BURLINGAME, M.D.
Hartford, Conn.

These past years, especially the war years, have been significant in bringing psychiatric facts and fancies to the fore. After a century of ostracism, psychiatry has found itself accepted almost over night in the home, in industry, in the schools and in the community. Actually, it has come to be quite the fashion to have a psychoneurosis!

In spite of this sudden rise to fame and fortune, psychiatrists might do well to examine themselves carefully to make sure that they are headed in the right direction. As chairman of the Committee on Public Education of the American Psychiatric Association and as president and psychiatrist in chief of a psychiatric hospital, I constantly receive communications expressing views on psychiatric matters from individuals and groups in my own country and abroad. These spontaneous remarks encompass most of the prevailing views on psychiatric developments, from which one can hazard a fairly good forecast of probable things to come.

There are many favorable indications that great progress has been made, but I am also convinced that, in spite of surface indications, psychiatry is not necessarily assured of smooth going from now on. Rather, there are matters not entirely desirable which call for serious, immediate attention.

Paradoxically enough, the matters which are not entirely desirable may be related to the popularity which has come to psychiatry so suddenly and unexpectedly. There is real danger in letting this sudden rise to fame and fortune "go to one's head"!

Psychiatry was born out of the jails and almshouses and probably had a more ignoble birth than the other branches of medicine. Subsequently, the struggle to establish psychiatry as a scientific practice related to the rest of medicine has met with more obstacles than has that of the more prosaic, less dramatic specialties such as cardiology, pediatrics or dermatology. In the not too distant past the psychiatric institution was separated from the life of the community. The psychiatrist was little more than a keeper of the keys who, if he did emerge from his walled abode, was looked on as some one who spoke a language different from others and spoke of things unrelated to society outside of the asylum.

Yet in the face of public rebuffs and an almost complete lack of monetary support, a relatively small group of psychiatrists and other earnest people have worked untiringly to learn more about mental illnesses. They have struggled to provide better care for psychiatric patients and to place psychiatry on a scientific medical basis.

It has been a hard struggle and a long one. Now, with the spotlight on psychiatry, the temptation is great to rush to the center of the stage; and this is the time that psychiatrists must avoid overplaying their part and, incidentally, suffering the consequences.

I am sure that all will concur when I say that it is psychiatric nonsense to claim that present day psychiatry contains the cure for all the mental ills to which the human flesh is heir. It is psychiatric nonsense to claim that if psychiatry only had a chance a vast majority of psychiatric breakdowns could be prevented.

In answer to the sudden and flattering demands on psychiatric services, one might better become increasingly realistic and answer the question: "What is actually known of preventive psychiatry in the sense that the rest of the members of the medical profession, as well as the laity, use the term preventive medicine?" Largely through preventive medicine, the span of life in America has been lengthened 20 years within a single generation. What does psychiatry have to offer today that is at all comparable to that?

It is true that the psychiatrist has many impressions about what is good for the mental health of the human being. It is true that he entertains many hunches about what will alleviate psychiatric illnesses, which comprise the greatest of all public health problems. However, it is also true that, with comparatively few exceptions, he does not know the cause of so-called mental diseases. Most diagnostic terms are only descriptive of conditions and do not yet represent disease entities in the same sense that pneumonia, typhoid fever and similar diagnostic terms represent disease entities.

For example, what is manic-depressive psychosis? What is its cause and how can it be prevented? What is dementia precox? What is its cause and how can it be prevented? I doubt if the endless papers describing these conditions are getting at the fine point of establishing disease entities, and the establishment of disease entities must antedate any truly scientific exploration into the causes and prevention of mental diseases.

It is only during the past fifty years that the great scientific discoveries have been made in psychiatry, and all in all science is a plodding, painstaking process which must be accepted if psychiatry is to be established on an enduring basis.

There is the matter of the forms of treatment. Therapeutically, psychiatry has made great advances since I first entered the field thirty-eight years ago. I have seen fads of all kinds come and go. I have

---

Read at the Primer Congreso Medico Social Panamericano at Havana, Cuba, Dec. 6, 1946

From the Institute of Living, the Neuropsychiatric Institute of the Hartford Retreat (president and psychiatrist in chief).

seen the intestines removed and thrown away. I have lived through this era and that era of enthusiasm about one form of therapy or another form of therapy, and I have seen them discarded.

Consider the present day shock therapy. Only a stupid person would decry shock therapy as an instrument in helping the mentally ill, but nevertheless one should not condone the use of shock therapy for everything from an ingrowing toenail to baldness. The seemingly miraculous results obtained in the presence of shock therapy should not cause one to lose the wits with which one was born or the knowledge one has acquired in the past thirty or forty years. To proceed as if shock therapy, any more than any other psychiatric technic, can usurp the place of all other therapies is psychiatric nonsense.

Also, lobotomies or leukotomies are coming forward. Because of their grave danger and high demands on the resources at the command of the psychiatrist, they probably are destined never to be a runaway; but again, to assume that the surgical procedure of the lobotomy replaces the usefulness of all other therapeutic technics and amassed psychiatric knowledge would be psychiatric nonsense.

Psychiatrists talk at great length about psychotherapy, which may convey a great deal to their own initiated group, but in the minds of the general public the term is more or less mixed up with metaphysics and the occult.

It is my own personal belief that psychotherapy, regardless of the form it assumes (and it does assume many forms), is essentially personal tutoring. Further, I believe that sound physical medicine and psychotherapy in the form of personal tutoring occupy the front ranks in the help which may be offered to the mentally ill. Other therapies are important adjuncts, but psychotherapy, in the form of personal tutoring, and sound physical medicine are a reliable basis for all present day psychiatric treatment aimed at restoring psychiatric patients to society.

A patient can be taken into a psychiatric institution and his psychiatric disorder can be alleviated by protecting him from the sin and suffering in the outside world and applying any one or several of other psychiatric treatments. But unless that patient is better equipped, when he leaves the institution, to cope with his problems outside the institution, treatment has been a failure. Nine times in ten the factors in his breakdown were concerned with his inability to cope with life as it exists outside the institution, and the defects within persons which make them unable to cope with life are as varied as human nature itself.

If a patient is ever to fulfil his destiny as a member of society, he must be trained to develop and to use his mental and physical resources in the world as it exists outside the mental hospital. If he is able merely to adapt himself to life inside the mental hospital, treatment has been unsuccessful. Psychiatric patients must be examined from the point of view of the human mind and the human body and must be put in the best possible condition to meet life. In a word—they must be reeducated for living.

In past years the psychiatrist has expended great kindness on the patients in mental hospitals, but let past procedures be examined to see if, with all this kindness, he has not expended all too little intelligence.

I urge a period of self analysis to see if the procedures used have not in a large measure been a desocializing influence, tending to train patients away from the methods and practices of society outside of institutions.

For example, how many patients have been making baskets, weaving rugs and polishing the floors in the hospital? How many of those same patients will make baskets, weave rugs or polish floors in their communities if the psychiatrist succeeds in sending them home?

To the extent that patients are exposed to any procedures foreign to their lives outside of the hospital, one may be guilty of doubtful practice. Indeed, in some instances it might well be asked if one is not unconsciously institutionalizing the patients; and institutionalizing the patients is extremely easy, even while one is all kindly feelings and charitable intent. But is this good treatment?

Psychotherapy in the form of personal tutoring is education in its broadest sense and has evolved in the United States into a technic known as reeducational therapy, with decidedly practical applications to normal living.

Of what does this reeducation consist? To answer that question, I am going to consider man's psychologic life under four practical headings: (1) his vocational life; (2) his avocational life; (3) his social and recreational life, and (4) his physical self.

Vocation.—First of all, man has a need to be of some use to others. He has a psychologic need to feel reasonably justified for taking up space on the good earth. The housewife who keeps a good home, the secretary who serves her employer, the truck driver, the electrician, the doctor—each is fulfilling a useful and responsible place in society. This is the vocational aspect of life.

Avocation.—The concept of avocations is that they are "secondary vocations." Most persons are not fortunate enough to do for a living that at which they would like to play, so they must have avocations or hobbies to satisfy their urge to be usefully interested in life. Avocations are those things which man does by himself as a hobby.

Social and Recreational.—Third, man is a social animal with a need to play and enjoy the lighter side of life. He needs to do things with other people. He needs their company and he needs to know how to get along with them.

Physical.—Of course, man must be physically well and physically fit. He must have good habits of taking care of the human body, which is the vehicle of his mind. It has often been said that a healthy body is necessary for a healthy mind.

To recapitulate, a human being sits psychologically on a four-legged chair. One leg of that chair is his vocation; another leg is his avocation; the third leg of that chair is the social and recreational leg, and the fourth is his physical self. If his chair has four solid legs, he is destined to sit comfortably and securely throughout life. If one leg is too short, or missing, he may well find a reasonable amount of security in his particular chair of life. If two of the legs are defective, he will probably be uncomfortable; and some people seem to have all four legs of different lengths, or some entirely absent, which leaves them precariously balanced, with the result that they fall.

For the moment I shall put aside theoretic thinking in the field of psychiatry, dispense with wishful thinking and get down to the known facts. Let psychiatrists make sure that these facts are used as the basis for the things which are still in doubt.

I have already intimated that one must first learn the physical condition of every psychiatric patient. At the Institute of Living in Hartford, Conn., with which I have the honor to be associated, more than a thousand new patients were received in the past year. As a routine, every patient has a complete physical examination, roentgenograms of the head, the chest, the heart and the lungs. Every patient has an extensive examination of the eye, the ear, the nose and the throat, the blood and the body fluids, electroencephalograms, electrocardiograms and all the neurologic and other physiologic examinations and tests. To the extent of present day diagnostic methods, no effort is spared to determine the physical condition of the patient at the time he is received, regardless of what the so-called psychiatric diagnosis may be. In addition, every patient is routinely exposed to a battery of psychologic tests.

It is interesting to note that two thirds of all the patients admitted have some demonstrable physical irregularity. At times the connection between the physical irregularity and the mental condition is quite obvious, but in a large percentage of the cases the connection is a matter of present and future research.

It is interesting to note that among 1,000 cases, thorough examinations indicated 8 brain tumors, which diagnoses were confirmed on the operating table. The psychiatric diagnoses of these patients had been psychoneurosis, dementia precox, reactive depressions and manic-depressive psychosis.

The accumulation of thousands of careful physical examinations on thousands of mental patients provides a fruitful field for research in the future, but I shall resist the temptation to guess what these studies may reveal as to the causes of mental diseases and their possible treatment. I am sure that these studies of the human body and the human mind will eventually result in the cessation of talk about mental disease and physical disease as two separate things but will lead to the inclusion of both under the term, disease. During the thirty-eight years I have been in the field of psychiatry, I have come to the conclusion that there is no such thing as "mental" disease in the sense in which the term has been used for several generations.

If one has a carbuncle on the back of the neck, one will refer to it as a physical disease, but is one's psychologic side changed? Of course it is. Is the personality of the dyspeptic changed? Of course. The change is so well known that the distorted personality of the dyspeptic is a common subject in the funny papers. Is the personality of a patient with typhoid changed in the midst of his delirium? Of course it is. The most psychotic patient I have ever seen was in the delirium of typhoid fever.

When I entered the field of psychiatry, dementia paralytica or softening of the brain was accepted as a "mental" disease. Then I had the pleasure of looking at the original slides in which the spirochete of syphilis was discovered in the cortex of the brain of a patient with dementia paralytica, revealing that this entity is syphilis of the brain. Is that a mental disease, or is it a physical disease?

There is a large group of patients with involutional melancholia. It is now known that in involutional melancholia there is an endocrine imbalance, the correction of which is the most immediate feature in the cure. Is involutional melancholia a mental disease or a physical disease?

I have seen dementia precox occurring in patients with pellagra. With the cure of pellagra, the dementia precox disappeared. Was that a mental disease or a physical disease? I have seen dementia precox in army patients who had long had malaria. With the cure of the malaria, the dementia precox disappeared. Was that a mental disease, or was it a physical disease?

Think of man as a whole. Think of his physical and mental incapacities as diseases, not separately as physical diseases or mental diseases. I fully believe that any other type of thinking will be referred to in the future as pure psychiatric nonsense.

However, there is a long gap between present day knowledge and the knowledge of a decade hence. Within that period, there are patients to be treated.

I doubt if merely talking with a patient, using so-called psychotherapy regarding hidden experiences which occurred to him at 2 or 3 years of age, is a practical solution to the problems of the hundreds of thousands of psychiatric patients. More is known about the course of the so-called mental diseases than about their causes. Happily, more is known about what can be done for so-called mental disease than about the exact nature of the disease.

A person may be born with a curved spine or weak eyes. Physicians can examine his spine and do a great deal to strengthen it. What is more, that person can be taught to live a useful and successful life with that handicap. By study of a patient with weak eyes, the defect can sometimes be corrected with glasses and that person can be taught to be a useful member of society. It is also true that one can study psychiatric patients as to their vocational past and their vocational possibilities and train them along vocational lines, so that they can live successfully in line with their vocational capacities and limitations. One can study their avocational past and their avocational possibilities and help them to develop these potentialities. One can study their social and recreational past and train them along these lines to enable them to live successfully according to their capabilities in a social and recreational way. And one can certainly study their physical selves and aid in their development so that they can live according to their physical capabilities. These things can be done; if one does them, it makes psychiatric sense and not psychiatric nonsense.

If psychiatrists will aid in the development of their patients vocationally and avocationally, socially, recreationally and physically, theirs will be a practical approach to the cure of psychiatric disabilities. If that is used as a basis for the attack on psychiatric diseases, one may have a clear conscience if one wishes to add any of the purely theoretic approaches. On the other hand, the psychiatrist is failing in his responsibility if he neglects proven facts and follows exclusively any of those schools of psychiatric thought which are based primarily on hypotheses.

There is no such thing as a scientific psychiatric approach which does not have a solid demonstrable fact as its point of departure. Theories and hypotheses are stimuli for research, but theories and hypotheses based on other theories and other hypotheses are not scientific facts. If the psychiatrist is lost in a morass of theory, there is great danger that his ideas of scientific advances will drift into the sphere of wishful thinking and fairy tales. A psychiatrist must first of all be a good physician with a complete knowledge of the human body and must use his knowledge in treating his patients. Second, he must be a bit of a sociologist who is a constant student of the milieu in which his patient has lived and must live in the future. Third, he must be a psychologist who understands the workings of the human mind. Fourth, he must be a specialized type of educator and fifth, he must be a vocational guidance expert. Any psychiatrist who does not fulfil all five of these intellectual disciplines is destined to fall short of his possibilities.

Most important of all, the psychiatrist must express himself in terms which can be understood by every medical practitioner, and psychiatry must be made an integral part of medicine. It does not take a great mind to make simple things complicated, but it takes a very great mind to make complicated things simple. Let psychiatrists, then, distinguish between psychiatric sense and psychiatric nonsense and bring simple, hard-headed sense into this field, which contains the greatest public health problem in the world today.

RHEUMATIC FEVER

Its Recognition and Treatment

GEORGE C. GRIFFITH, M.D.
Pasadena, Calif.

The importance of rheumatic fever is indicated by the fact that 2 per cent of the school children of the United States have heart disease as a result of the rheumatic state; that the cause of 98 per cent of all heart disease in patients under 20 years of age is rheumatic fever; that rheumatic fever causes more deaths in the first two decades of life than all of the communicable diseases plus pneumonia; that rheumatic fever causes annually ten times as many deaths as infantile paralysis, and that a study of the young men rejected for military service because of heart disease showed the rheumatic state to be the etiologic factor in 51 per cent in Boston, 70.3 per cent in Chicago, 64.4 per cent in New York, 65.9 per cent in Philadelphia and 39.6 per cent in San Francisco (White, Levy and Stroud [1]). Its importance is further emphasized by the recent knowledge that rheumatic fever is not a disease confined to the temperate zone but is almost as prevalent in subtropical climates as in the temperate zones (Sampson [2]) and that even the acute fulminating type of the disease is frequently seen in the tropics (Huntington [3]). The belief that the disease is confined to the temperate zone arises from the more frequent occurrence of the severe types in that zone. This important disease has now become a global problem.

Hereditary susceptibility to the disease, previously thought to be of a mendelian recessive character (Armstrong and Wheatley [4]) may be largely due to poor nutrition or to group crowding, as shown by the experience of the Army and Navy in training centers. Good nutrition and segregation may be a large factor in protecting the individual from an inciting agent such as the beta hemolytic streptococcus (Wilson [5]). It is true that children of parents who have had rheumatic fever are more susceptible to the development of the disease in the presence of an infection due to hemolytic streptococcus, i. e. tonsillitis, scarlet fever and otitis media, than are the children of nonrheumatic parents (Paul [6]).

DEFINITION

From the combined experience of the clinician, pathologist, bacteriologist, allergist, neuropsychiatrist and dermatologist working with this disease in a large group of patients of military age, a consensus has gradually developed that this disease entity is best characterized by the following definition: Rheumatic fever is a systemic poststreptococcic nonsuppurative inflammatory disease with protean manifestations of varying severity and duration. Pathologic, histologic and clinical observation shows that the disease is a hypersensitivity angiitis manifest in all of the bodily structures from the skin to the smallest subdivision of the viscera.

THE PHASES OF THE RHEUMATIC STATE

The first phase of the disease is that period of illness during which the patient is the host to the beta type of the hemolytic streptococcus. From military experience it has been learned that 5 per cent of trainees develop a suppurative hemolytic streptococcic infection in the upper portion of the respiratory tract. This infection may take the form of a pharyngitis, tonsillitis, otitis media or a sore throat with scarlatiniform rash, the so-called scarlet fever. In approximately 5 per cent of this group of patients the symptoms and signs of rheumatic fever develop. Therefore it is logical to consider every patient with a throat infection due to hemolytic streptococci, a potential rheumatic fever subject. In those susceptible persons in whom rheumatic fever develops it is proper to consider this the first phase of the disease.

The second phase is the period of latency which is from one to four weeks in duration. It is during this, the second phase of the disease, that the patient develops a hypersensitivity, is found to tire easily, may run a mild fever and have a persistent leukocytosis, elevated blood sedimentation rate and a gradual increase in the level of the antistreptolysin titer (Rantz [7]). This second phase is frequently observed only as an interval of time. The painstaking physician will find that the patient is not symptom free and is developing the rheumatic state.

The third phase is the well known period of rheumatic fever activity. The protean manifestations may be grouped into four distinct types, each of which with its symptom complex will be described in detail subsequently. The severity and duration of this phase of activity cannot be predicted, as the most fulminating onset may be followed by a relatively short period of activity, for example, from four to six months, while in the subclinical type activity may persist for years.

The fourth phase is the period of rheumatic fever inactivity. It is the period of the arrested rheumatic state, or the period of rheumatic quiescence. This phase of the disease may be long or short, depending

on reactivation of the rheumatic state. The mild pain occasioned by muscle jelling, articular stiffness and soreness resulting from fatigue or exposure do not constitute a reactivation of the rheumatic process. An infection of the upper respiratory tract followed by fever, tachycardia, malaise, dyspnea and migrating polyarthritis and concomitant laboratory observations of an increased blood sedimentation rate, leukocytosis and electrocardiographic changes constitute a reactivation. Of a large number of patients returned to a rheumatic fever unit for supposed reactivation, only 2.4 per cent were found to have a reactivation. Thus, the fourth phase of the disease begins with the termination of rheumatic fever activity and ends only if reactivation occurs.

ONSET OF THE RHEUMATIC STATE

The beginning of the active stage of rheumatic fever may be insidious and go unnoticed and undiagnosed for a long time, as shown by the survey of rejectees with cardiovascular disease (Levy, Stroud and White[1]). It was found that 71.2 per cent of patients in four cities and 50 per cent in two cities did not give a history of acute rheumatic fever. On the other hand, the onset of the rheumatic state may be severe. The younger the patient the more severe the onset appears to be the rule. The latency phase of the disease is ended by an acute illness characterized by migrating polyarthritis, fever, shortness of breath, tachycardia out of proportion to the rise in temperature, loss of appetite and severe sweats. The patient is restless but moves the extremities little because of painful joints. The face is flushed. The tongue and lips are dry. The skin is hot and dry, alternating with periods of drenching sweat. The migrating polyarthritis usually begins in the larger joints, such as the knees, ankles, elbows, wrists and at times the hip and shoulder joints. The periarticular tissues are swollen, hot and tender. As the process begins to subside in one joint, it often lights on a contralateral joint. The polyarthritis persists a relatively short time after the patient has been put to rest. The administration of salicylates sufficient to raise the blood level to 30 mg. per hundred cubic centimeters of blood relieves the polyarthritis promptly. Patients with sedentary duties do not develop the severe articular manifestations which characterize the physically active group.

The fever may be absent, moderate or severe. The severely elevated temperature persists for ten to eighteen days and then gradually subsides, or it may continue at a low level for months. The shortness of breath is usually overlooked. It is common in the acute stage and is the first sign of myocardial failure and/or rheumatic pneumonitis. The tachycardia is out of proportion to the degree of fever. Even though fever is absent, a tachycardia is usually present. The tachycardia persists as long as there is activity present.

During the acute onset, carditis is shown by dilatation and gallop rhythm; electrocardiographic changes may be present. Pericarditis as indicated by a to and fro friction rub or by an effusion is not frequently diagnosed. In a large series of patients it was diagnosed clinically in 2.82 per cent of cases. Endocarditis is diagnosed only with caution in the active phase when (1) the murmur is diastolic in time; (2) a systolic murmur persists through six months' observation; (3) the systolic murmur remains the same or grows worse in intensity and is heard in all positions and in all phases of respiration; (4) the systolic murmur is transmitted. These signs of carditis may be present early in the acute onset but most frequently are later manifestations.

Pneumonitis was found in 11.3 per cent[7a] of 1,046 patients with prolonged rheumatic fever. The symptoms of rheumatic pneumonitis in the order of their frequency are shortness of breath, tachycardia, fever, pleuritic pain, malaise and cough. The shortness of breath and tachycardia may precede the fever, pleurisy and cough by many hours to a few days. Physical observation shows small areas of dulness and diminished breath sounds anywhere in the pulmonary fields. Fine rales soon appear. The patchy areas of pneumonitis shift from one site to another. The upper lobes of the lungs are involved as frequently as are the lower lobes. A pleural effusion may appear rapidly. It disappears with equal rapidity unless congestive failure supervenes. Thoracentesis, like pericardial drainage, is seldom necessary. The roentgenologic observations of rheumatic pneumonitis are those of so-called primary atypical pneumonia. The pathologic histology is that of a pulmonary angiitis with multiple small infarctions.

Loss of weight and loss of appetite are common at the onset. The return of appetite and a gain in weight are good indexes that the rheumatic activity is subsiding.

Abdominal pain is due to localized peritoneal inflammation resulting from the angiitis in the parietal and visceral peritoneum. Confusion with acute appendicitis is not frequent. More frequent is its association with liver engorgement. In the acute onset of rheumatic fever abdominal pain is frequently due to diaphragmatic pleurisy or to peritoneal irritation. Usually the dyspnea, tachycardia, signs of pneumonitis or carditis and polyarthritis are out of proportion to the abdominal pain. If the abdominal pain localizes and the classic picture of acute appendicitis persists, then surgical intervention should be undertaken. The problem of acute appendicitis at the onset of acute rheumatic fever was not frequently encountered. Acute appendicitis during the prolonged period of convalescence did not exceed the expectancy in a similar age group of nonrheumatic fever patients.

Chorea at the onset of acute rheumatic fever is extremely infrequent in patients of military age. In only 0.04 per cent of rheumatic fever patients did chorea develop at any time during the period of observation.

At the onset of the disease erythemas are frequent. The erythemas are those of a hypersensitivity, varying from erythema marginatum to urticaria. Erythema multiforme and erythema nodosum are not specific manifestations of rheumatic fever activity.

Subcutaneous nodules are not frequently seen at the onset in patients of military age. Subcutaneous nodules when present indicate a severe rheumatic activity.

Epistaxis is common at the onset of the disease in children. In the age group from 18 to 25 years 0.3 per cent of patients show this phenomenon. However, in another study Montgomery[8] has shown that there is a definite increase in capillary permeability and fragility in persons in the rheumatic state.

Concomitant with the onset of the disease there is an increase in the leukocyte count and an elevation of the blood sedimentation rate and of the antistreptolysin titer. None of these observations are specific for the rheumatic state.

THE CLINICAL TYPES OF RHEUMATIC FEVER

There are four clinical types of rheumatic fever recognizable, namely, the acute fulminating, the subacute polycyclic, the subacute monocyclic and the subclinical.

Acute Fulminating Type.—The acute fulminating type was found to occur at a rate of 4.3 per cent in a series of patients who showed evidence of rheumatic activity for more than six months. This type is frequent in childhood. The acute fulminating type is characterized by a sudden onset with migrating polyarthritis, fever, restlessness, severe tachycardia, dyspnea and drenching sweats. Carditis appears rapidly as shown by dilatation, gallop rhythm, murmurs and at times pericarditis. Pneumonitis is present in many patients. Pneumonitis can be detected by careful physical examination but is more frequently diagnosed by the roentgenologic studies of the lungs. The migrating polyarthritis is of short duration although usually severe at the onset. The temperature is relatively high, ranging from 101 to 103 F. The acute febrile period lasts from ten to eighteen days and then subsides with a rapid convalescence or goes into a prolonged low grade state of activity. The tachycardia is decided and is the last sign of activity to disappear. The leukocyte count is moderately elevated with a great increase in the granulocytes. The urine may contain albumin and a moderate number of cells. Approximately 20 per cent of patients in this group show electrocardiographic changes indicative of myocardial and pericardial involvement. The acute fulminating type of disease usually terminates with one cycle. This group represents those patients who are most susceptible to the disease. Although the mortality is low in the primary attack, this type is more liable to reactivation.

Subacute Polycyclic Type.—The subacute polycyclic type is similar to the acute fulminating type at the onset except that it is less severe. It occurs more frequently. The percentage of occurrence in this series of patients was 27.6 per cent. The cycles may be short and spaced at long intervals, or in the more severe subtypes the cycles may be long and spaced at shorter intervals of time. It is in this type of rheumatic fever that the mortality is the greatest. In this series of patients 63.6 per cent of the fatalities occurred in the subacute polycyclic type of the disease. Likewise in this group with repeated cycles of activity the most extensive cardiac enlargement and the most frequent signs of endocarditis and pericarditis are found. During one or all of the cycles pneumonitis of greater or less degree may occur. After the first cycle, polyarthritis is usually absent and the response to salicylate therapy is poor. Congestive heart failure complicating carditis occurs almost exclusively in this group of cases.

Subacute Monocyclic Type.—The subacute monocyclic type, the most frequently observed of the four types, occurred in this series in 61.3 per cent of the patients. The onset may be mild and scarcely recognizable, or it may be moderately severe with moderate fever, mild migrating pains, a definite tachycardia and moderate elevation of the leukocyte count and blood sedimentation rate. The response to salicylates is usually prompt, and the acute onset lasts for seven to fifteen days. Thereafter the course may be that of a rapid return to the stage of quiescence so that full duty may be resumed in from four to six months; or the course may be long with signs of mild activity persisting over a period of six to nine or more months.

Subclinical Type.—The subclinical type was found in 5 per cent of the cases. This group comprised those patients who may or may not have had an infection of the upper part of the respiratory tract and who in the course of a follow-up examination were found to have definite signs of rheumatic heart disease. Such signs are those of enlargement of the cardiac chambers, mitral and/or aortic insufficiency murmurs, paroxysmal tachycardias and auricular fibrillation. On careful observation this group of patients exhibited a few signs of rheumatic activity, such as a cyclic low grade temperature and a mildly increased sedimentation rate. At other times confirmatory evidence of rheumatic activity was not found. Two patients within this group died suddenly. Death in each instance was due to an acute angiitis with a collagenous change in the coronary arteries sufficient to cause an occlusion and myocardial infarction.

THE CRITERIA FOR THE DIAGNOSIS OF RHEUMATIC FEVER

The diagnostic criteria for rheumatic fever have been previously laid down by Swift[9] and Jones.[10] They are subdivided into major and minor groups: The major criteria are five in number, namely, a history of a previous attack, carditis, fever, migrating acute arthritis and chorea; the minor criteria in the order of their relative importance are pneumonitis, tachycardia, subcutaneous nodules, erythemas, epistaxis and purpura, loss of weight and abdominal pain.

MAJOR DIAGNOSTIC CRITERIA

A previous history of rheumatic fever was obtained in 28.1 per cent of the patients. Too often, however, mild arthralgia and muscle jelling are mistaken for a previous history. A previous history is of great diagnostic helpfulness when a patient presents himself with only one or two of the major criteria and two or three of the minor criteria.

Carditis is probably the most important of the major diagnostic criteria. Carditis can be said to be present when a tachycardia, especially a resting pulse rate of 100 or more, persists; when there is dilatation of the heart as shown by enlargement and/or gallop rhythm; when pericarditis is evidenced by a to and fro pericardial friction rub and/or a pericardial effusion; when myocarditis is demonstrated by dilatation, gallop rhythm and electrocardiographic changes, and when endocarditis is established by hearing definite organic cardiac murmurs.

Fever is considered the most frequent evidence of an active rheumatic state. It is the most reliable evidence of activity in the absence of demonstrable carditis. At the onset the temperature range may be normal or, as in the severer types, as high as 102 to 104 F. The degree of fever is not the paramount observation, but persistence of the fever is of utmost importance. No clinician can be sure that activity has ceased unless a carefully taken and recorded temperature curve has been observed for at least six to eight weeks' time. Persistent fever in the subacute types of the disease takes one of two forms. The more frequent form is an evening rise in temperature to 99 or 100 F. The more insidious and most frequently unobserved form is a cyclic type of curve. In this form the temperature remains at a normal or a slightly subnormal level for one to two weeks and then becomes mildly elevated for a few days or as long as a week. Fever is seldom the only evidence of rheumatic activity. Persistent fever must be viewed seriously especially if two or more minor criteria are present.

[10] Jones, D. E., cited by Stroud, W. D.: The Diagnosis and Treatment of Cardiovascular Disease, Philadelphia, F. A. Davis Company, 1940.

Polyarthritis, or migrating acute arthritis, for over three centuries has been considered the significant sign of the disease. In recent years the literature has emphasized the unimportance of the articular signs. In the primary attack the signs related to the joints are usually prominent and frequently constitute the presenting symptom and sign. The major joints become red, hot and swollen in a migrating fashion. With rest the articular signs disappear quickly. The salicylate compounds in adequate dosage are specific and prompt in action. The red, hot, swollen joints subside, leaving no residual pathologic conditions. In those patients in the third decade of life arthralgia may persist. The persistent arthralgia is not considered a sign of activity when all other criteria have disappeared. If one major or two minor criteria persist, then the complaint of painful joints must be considered as evidence of rheumatic activity.

Chorea is a relatively infrequent disease in the second and third decades of life. It has occurred in this series of patients in 0.047 per cent. None of the cases have exhibited the severe choreiform movements seen in childhood. There have been other neurologic manifestations occurring during the active course of the disease. In 2 patients temporary hemiplegia developed with gradual complete recovery. In 6 patients there developed unilateral or bilateral involvement of the brachial plexus varying from weakness and pain in the entire upper extremity to wrist drop. In 2 patients there developed temporary foot drop. These neurologic signs were not considered of psychic origin. With continued treatment of the rheumatic state the organic neurogenic signs cleared up promptly.

MINOR DIAGNOSTIC CRITERIA

The minor criteria in the order of their relative importance are herewith described.

Pneumonitis.—Pneumonitis was overlooked by most American clinicians until Boas and Schwartz,[11] Paul,[12] Swift,[9] Coburn [13] and Gouley and Eiman [14] called attention to the clinical and pathologic findings. The constant occurrence of pneumonitis in the acutely ill and the frequency with which it is found in the relatively mild stages of rheumatic activity emphasize its importance. Frequently the chief complaint of the patient is dyspnea and the first outstanding sign is that of pneumonitis; likewise it is frequently the first sign found in a current cycle and in a reactivation. When the roentgenologic examination of the lungs simulates an atypical pneumonia and the sputum yields no specific organism in a rheumatic fever patient, the diagnosis of rheumatic pneumonitis is considered established.

Tachycardia.—Tachycardia is a minor diagnostic criterion which, if constant and persistent during sleep, is of positive value. Paroxysmal tachycardia and auricular fibrillation were infrequent in this series of patients.

Subcutaneous Nodules.—Subcutaneous nodules are not seen frequently. They are a definite sign of activity. In the past their significance has been considered ominous, but perhaps this has been because they were not looked for carefully in the subacute and mild cases. They are a diagnostic sign but do not carry the poor ultimate prognosis formerly attributed to them.

The Purpuras and Epistaxis.—There is a definite increase in the fragility and permeability of the capillaries in the rheumatic subject. Purpuric manifestations are seen but seldom. Not over 0.3 per cent in the entire series showed purpura. Epistaxis is of similar significance and occurs infrequently in patients in the second and third decades of life. When purpura is present it is a helpful diagnostic sign.

Loss of Weight.—Loss of weight is a common occurrence in the acute phases of the active state and gain in weight is commensurate with the improvement in the patient.

Abdominal Pain.—Although abdominal pain has been considered of great importance in the literature, it is a relatively uncommon occurrence late in the disease. At the onset of an acute episode there may be abdominal pain without definite signs of localization, but if there is a previous history of rheumatic fever and the shortness of breath and tachycardia seem out of proportion to the fever of the patient, and especially if there are articular manifestations, it is safe to wait and watch; but if appendicitis cannot be ruled out, then perform a surgical operation, as the risk is small.

Recurrent Cycles.—Recurrent cycles of rheumatic fever may be initiated by surgical procedures such as dental extractions or tonsillectomy. The fracture of bones is almost sure to set up a recurrent cycle of activity. Fractured bones must be firmly fixed as soon after fracture as possible. It is unwise to extract teeth or to perform a tonsillectomy until six months has elapsed after all signs of activity of the rheumatic process have ceased.

Laboratory Data.—Results of laboratory tests are helpful but not specific in rheumatic fever. There is no specific laboratory diagnostic test.

Anemia.—The secondary type of anemia may develop rapidly in the extremely acute forms of rheumatic fever. In the mild types of the disease anemia is uncommon.

Leukocytosis.—The white blood cell count during the acute onset may be as high as 15,000 to 24,000 with as much as 90 to 95 per cent polymorphonuclear leukocytes. In the subsiding stage the leukocyte count falls rapidly to normal and is not a reliable index to the degree of activity.

Antistreptolysin Titer.—The antistreptolysin titer is elevated at the onset of disease and continues to remain elevated for a long time. Because of the technical difficulties of the determination and because the titer remains elevated after other signs of activity have disappeared, it is not a satisfactory guide as to the degree of activity or the indicated treatment. Its greatest value is in the etiologic study of rheumatic fever.

Blood Sedimentation Rate.—The sedimentation rate is elevated during the phase of rheumatic activity. It is the best single guide to the degree of such activity.

---

[11] Schwartz, S. P., and Boas, E. P.: Am. Heart J. **2**: 375 (April) 1927.

[12] Paul, J. R.: Medicine **7**: 383 (Dec) 1928.

[13] Coburn, A. F.: The Factor of Infection in the Rheumatic State, Baltimore, Williams & Wilkins Company, 1931.

[14] Gouley, B. A., and Eiman, J.: Am. J. M. Sc. **183**: 359 (March) 1932.

If the sedimentation rate remains elevated when all other signs of activity have disappeared, then the clinician must rule out other causes for an increased rate of sedimentation.

Electrocardiographic Changes.—There are three electrocardiographic changes indicative of carditis: first, a shifting auriculoventricular conduction time, especially if the PR interval is well over 0.24 second. This change is seen in varying degrees up to the Wenckebach phenomena and complete auriculoventricular dissociation; second, the typical electrocardiographic picture of pericarditis; and third, the QRS and T wave changes which are seen in myocardial damage resulting from the anoxia of coronary insufficiency. The coronary insufficiency is the direct result of coronary arteritis of moderate to severe degree.

Urinary Changes.—The urinary changes in rheumatic fever have been minor and notable for their absence. In the acute phases of the disease the urinalysis may reveal albumin and a moderate number of cells; in the subsiding phase, the urinalysis is usually normal.

Causes of Death.—The frequency of death from the primary attack of rheumatic fever was small. Only 13 deaths occurred in over 10,000 rheumatic fever patients of military age. The causes of death in this group, in order of frequency, were congestive failure, pneumonitis, coronary occlusion with myocardial infarction, and shock resulting from necrosis of the adrenal gland.

THE DIFFERENTIAL DIAGNOSIS

Rheumatic fever in its acute form must be differentiated from undulant fever, rheumatoid arthritis, chronic osteoarthritis, tuberculosis, Reiter's syndrome and the collagenous diseases. This is best done by evaluating the previously outlined criteria and by close observance of the clinical course of the disease.

Undulant fever is ruled out by a persistently negative cross agglutination test and by the failure of carditis to develop.

Rheumatoid arthritis is difficult to differentiate early, but time with the visual as well as roentgenologic changes in the joints points to this entity rather than to rheumatic fever.

In osteoarthritis the development of roentgenologic evidence of articular disease and the lack of most of the major and minor criteria of rheumatic fever serve to make the differentiation early.

Tuberculosis is confused with rheumatic activity by the prolonged fever, but here again the absence of the other four major criteria and of most of the minor criteria rules out rheumatic fever.

TREATMENT

The essential problem in the treatment of rheumatic fever is the prevention of disabling heart disease. If the fulminating polycyclic type of rheumatic fever could be attenuated and shortened and if the monocyclic and subclinical types could be prevented from causing severe inflammatory-like reactions in the vascular tissues then disabling heart disease could be avoided. It is believed that angiitis may continue indefinitely after the initiation by an antigen-producing organism in the throat. Since there is as yet no effective method known to destroy the antigen-producing bacterial agent or to prevent the nonsuppurative inflammatory reactions in the vascular tree, there must be an alinement of all the available therapeutic agents to prevent death or at least to reduce cardiac damage to the minimum.

The treatment of the rheumatic state is divided loosely into two parts according to the stage of the disease—the stage of activity and the stage of quiescence.

The Stage of Activity.—The point at which the physician should start treatment of the active rheumatic state is difficult to determine. Every patient with an acute suppurative sore throat due to hemolytic streptococci is a potential subject for rheumatic fever. Observation of the patient with a hemolytic streptococci infection of the throat should be maintained over a longer period of time than that which is usual, in order to detect the onset of an active rheumatic state at the earliest possible moment. The patient who is slow in recovering from the acute throat infection due to hemolytic streptococci and who fatigues easily, having a slight evening fever, an elevated blood sedimentation rate and a high antistreptolysin titer, is one in whom rheumatic fever is likely to develop. With the onset of the active stage of rheumatic fever early recognition is requisite, and the patient should be placed immediately on a carefully planned and administered regimen.

Rest.—Absolute rest in bed is imperative and must be continued in varying degrees until the signs of rheumatic activity have disappeared. Rest means limited activity in bed, quiet surroundings conducive to sleep and diversionary interests. As the patient improves rest must be judiciously proportioned to the state of the disease.

Nursing Care.—Nursing care wisely and intelligently carried out does much to promote rest, sleep and mental diversion. A daily bath with tepid water, clean linen and attention to diet and to elimination are elementary but essential nursing services.

Diet.—The diet should be highly nutritious, of at least 3,500 calories per day given in liquid to soft or solid form dependent on the patient's temperature and general condition.

The Salicylates.—Only the salicylates have survived the test of time in the treatment of rheumatic fever. Most clinicians agree that the salicylates have an analgesic and antipyretic action in rheumatic fever. Few, however, feel that salicylates modify the progress of the disease process. Salicylates do relieve pain, lower the temperature and hasten the absorption of the transudate in the serous cavities during the first attack, but they have no apparent effect on the disease process after the sensitizing stage is passed. Furthermore, the salicylates have little if any analgesic and antipyretic effect in the second and third cycles and in the course of the prolonged monocyclic cases.

Salicylates in the form of sodium salicylate 25 grains (1.62 Gm.) and sodium bicarbonate 10 grains (0.65 Gm.) every four hours or acetylsalicylic acid 20 grains (1.29 Gm.) and sodium bicarbonate 20 grains (1.29 Gm.) every four hours, day and night, with 3,000 cc. of water, elevate the salicylate concentration to the optimum level of 30 to 50 mg. per hundred cubic centimeters of blood within twenty-four to forty-eight hours. If the salicylates are administered absolutely regularly with an adequate quantity of water the level in the blood remains at or near the optimum. The salicylates are promptly absorbed from the upper part of the gastrointestinal tract and appear in the blood within fifteen to thirty minutes, and the optimum level can be maintained with the aforementioned dosage. The excretion of the drug is rapid through the kidneys so that within twenty-four hours after the cessation of salicylate therapy little trace, if any, can be found in the blood. The drug may be administered in the form of the sodium or acetyl salts without alteration of the optimal blood level. The drug should never be given in the enteric-coated tablets, as it is absorbed from the upper part of the gastrointestinal tract, and if the enteric-coated tablets are slow in disintegrating in the colon a toxic dose may suddenly be absorbed from the accumulated tablets resting there.

The salicylates are unpleasant to take orally and may induce *tinnitus aurium*, burning of the eyes, sweating, cerebral excitement, irritability and irresponsibility, as well as gastric irritation. However, in the dosage mentioned such symptoms are infrequent. If the patient is ambulatory and signs and symptoms of salicylism develop, the return to rest promptly affords relief. Gastric irritation is readily avoided by the ingestion of an abundance of water and food with the drug. The only reason for the administration of sodium bicarbonate with the salicylates is to prevent gastric irritation. The hydrochloric acid of the stomach changes the sodium and acetyl salts to salicylic acid, in which form it appears in the blood. The use of somewhat smaller doses of sodium bicarbonate than those reported by Smull, Wegria and Leland[15] (1944) do not lower the blood salicylate level.

The intravenous administration of the drug is undesirable and unnecessary except in those rare instances in which salicylates cannot be given orally. When the salicylates are swallowed according to the aforementioned dosage, the level is consistently maintained. If the level is low the patient is not receiving the drug regularly; if the level is too high there has been an insufficient fluid intake. The administration of 1,000 cc. of a 1 per cent solution of sodium salicylate intravenously over a period of six to ten hours not only tires the patient but may throw an added strain on the right side of the heart. The administration of 10 cc. of a 10 per cent solution of the drug intravenously raises the level adequately and does no harm when given at the rate of 1 cc. per minute through a 26 gage needle but may sclerose the veins, making frequent administration difficult. In congestive failure of the heart there is slow absorption of the drug and salicylates do not benefit the patient materially. Salicylates per rectum are poorly absorbed. A study on the absorption of the salicylates shows that no appreciable amount of the drug reaches the blood stream when administered per rectum.[15a] Therefore oral administration is the method of choice.

Digitalis.—Treatment with digitalis is of doubtful value in the active stage of rheumatic fever. Its use is indicated only with the onset of congestive failure during the course of an active carditis. The drug is administered in full dosage orally. The method calls for a dosage of 1 U. S. P. unit per 10 pounds (4.5 Kg.) of body weight, adding 1 unit (1½ grains, 1 Gm.) for each additional day required to complete digitalization, and thereafter a maintenance dose of 1 U. S. P. unit is to be given daily. It has not been necessary to use digitalis or quinidine sulfate in the treatment of the infrequent instances of paroxysmal auricular fibrillation and the more infrequent cases of paroxysmal tachycardia, as these conditions subside spontaneously with rest. Quinidine is seldom used because of the infrequent occurrence of the paroxysmal tachycardias. Premature contractions occurring in the acute phase of the disease are not eliminated by the use of a daily ration of this drug. Rest and the avoidance of cigarets are measures which are of distinct value. Quinidine and *p*-hydroxy-*α'*-methylphenylethylamine hydrobromide have not been useeful in the correction of arrhythmias during the stage of carditis.

Oxygen.—Oxygen is of great value in the treatment of rheumatic pneumonitis and congestive failure. Restlessness, cyanosis, dyspnea and even tachycardia are helped by the administration of oxygen. Oxygen is given early and as long as the patient is embarrassed. It is easily administered by the nasal tube method, passing approximately 4 liters of oxygen per minute through a humidifier and into the nasopharynx. By this method the coldness of the oxygen tent is avoided, the patient is less annoyed and feeding and nursing care are rendered with greater ease. The saving in the amount of oxygen used is at least one half.

Diuretics.—Diuretics are used only when there is evidence of congestive heart failure. The diuretics are believed to be of greater value than any other drugs in the treatment of congestive failure in acute carditis. It has been observed that right-sided failure of the heart is frequently primary. It is believed that this is due to the associated rheumatic pneumonitis which decreases the vascular pulmonary tree to such an extent that the blood pressure in the lesser circulation is elevated and throws a marked strain on the right ventricle. The diuretics in the form of theobromine and sodium acetate in dosage of 7½ grains (0.49 Gm.) or theophylline ethylenediamine 3 grains (0.19 Gm.) four times a day are effective. If the engorged liver and the peripheral edema persist when absolute rest in bed, digitalis and xanthine diuretics have been used, then injection of the mercurial diuretics intravenously have been found helpful. In acute carditis the mercurial diuretics may produce anuria and therefore must not be used if there is evidence of renal impairment or inflammation.

Sulfonamide Drugs.—The sulfonamide compounds have been used in a large number of patients with rheumatic fever because of the apparent relationship between the streptococcic infection of the throat and the acute rheumatic state. Rheumatic fever patients with intercurrent tonsillitis, sinusitis or otitis media with positive hemolytic streptococcic cultures have been treated with a full dosage of sulfadiazine. The salicylates were continued at the same time. This method of treatment resulted in an appreciable increase in the number of rheumatic fever patients and in the number of recurrences.[7]

Penicillin.—Penicillin is not beneficial in the treatment of rheumatic fever. It is harmful when continued over a long period of time.[16] Penicillin is used in the treatment of the intercurrent infections.

Vitamins.—The food intake per patient should average 3,250 calories a day and since a varied diet is made available, supplementary vitamins should *not* be used routinely. In cases in which a patient has been seri-

ously ill and the dietary intake has been deficient, vitamins are added. The use of ascorbic acid has not caused a more rapid convalescence as indicated by a leveling of the temperature curve and the sedimentation rate. Ascorbic acid lessens gastric irritation. In a small series of cases of rheumatic purpuras, vitamin P (hesperidin) has not corrected or prevented the recurrent attacks of petechial hemorrhages.[17] Vitamin K and calcium in large dosage have likewise been ineffective in correcting the increased capillary fragility common to the rheumatic state.

Iron.—Iron is of value in the correction of the anemias secondary to the active rheumatic state. Ferrous sulfate 6 grains (0.39 Gm.) three times a day is adequate dosage.

Fever Therapy.—Fever therapy has not been evaluated. It has been shown by Sutton and others [18] that chorea clears up rapidly with fever therapy. Sutton's recent comparative study [19] of treated and untreated chorea patients has suggested that this form of therapy may have a beneficial effect on the severity of subsequent cardiac lesions. A high ketogenic diet and salicylate blood level have adequately controlled the choreiform symptoms.

Roentgen Therapy.—Roentgen therapy has been advocated in the treatment of the active phase of carditis by Levy and Golden.[20] On the basis of their work 201 cases of active rheumatic fever were selected. The criteria for selection were that the disease must have been active with one or more recurrences for six consecutive months and had not reached the quiescent state on the usual therapy. The case histories, physical findings and laboratory procedures were analyzed before roentgen therapy was initiated and again six weeks after the series of treatments had been completed. The roentgenologist did not know the state of activity of the disease in any case and administered 100 r through the myocardium weekly for five weeks to 71 patients, the same dosage through the myocardium and over the cervical sympathetic ganglions to 63 patients and no treatment to 67 patients. Thus 71 patients received treatment of 500 r to the myocardium; 63 received the same dosage to the myocardium and to the cervical sympathetic ganglions and 67 received no treatment. In the last group the exposed field was blacked out by a lead filter. Of the 71 patients who received treatment to the myocardium, 49.4 per cent obtained no effect; 47.2 per cent showed slight improvement and 1.4 per cent pronounced improvement. Of the 63 patients who received treatment to the myocardium and cervical sympathetic ganglions, 65 per cent showed no effect while 33.3 per cent showed slight improvement and 1.6 per cent definite improvement. Of the 67 who received no treatment except psychic influences 59.7 per cent showed no effect, while 29.8 per cent showed slight improvement and 10.4 per cent well defined improvement. From this study it is believed that roentgen therapy had no therapeutic effect against rheumatic fever. There may have been a slight psychogenic effect in that the patient thought something was being done for him.

Foci of Infection.—Removal of foci of infection is not attempted during the active phase of the disease. The removal of foci of infection would seem to be a logical procedure in the quiescent stage except for two factors: first, the difficulty in determining the point at which the disease is quiescent even though all clinical and laboratory criteria for such have been met; and, second, the frequency with which recurrences of the active phase have been noted following tonsillectomy or dental surgery. Statistical proof shows the undesirability of removing teeth or tonsils until at least six months have elapsed after the disease has been thought to be in the quiescent state.[20a]

Blood Plasma.—It is believed that blood plasma should not be used in the active phase of rheumatic fever. Seven out of 9 patients were definitely worse after the administration of pooled plasma.

Serums and Vaccines.—Serums and vaccines have proved disappointing in the past (Hitchcock, McEwen and Swift,[21] Wilson [22] and Coburn [23]). Therefore they have not been used or further investigated.

Treatment in the Inactive or Quiescent Stages.—The treatment in the quiescent stage differs from that planned for the active stage largely in degree. The periods of rest are shortened. The nursing care is limited to little beyond the recording of the daily temperature curve and the supervision of the reconditioning program.

Climatotherapy.—The exposure of the rheumatic fever patient to a warm, dry climate and regulated heliotherapy is of some general benefit. The hemolytic streptococcus does not die out in a warm, dry climate. The incidence of rheumatic fever in Naval training camps in the temperate zone has not been definitely greater than that in the training camps in the subtropical zone. The type of rheumatic fever differs, however. It is believed that a warm, dry climate has a beneficial effect on the disease. Exposure to sunshine, however, must be gradual and carefully regulated.

Physiotherapy.—Physiotherapy is definitely harmful in the transudative stage of the rheumatic polyarthritis. It is of value in the older age group when there is residual muscular weakness, jelling, arthralgia, fibrositis and bursitis.

Avoidance of Infection.—Since there is a direct relationship between the hemolytic streptococcic infection of the throat and rheumatic fever, every effort should be made to protect those patients who have had the disease. With the onset of an acute infection of the upper part of the respiratory tract rest in bed is essential. Isolation technic should be practiced and the patient treated with 300,000 units of penicillin daily for two or three days. Various procedures such as the oiling of floors and blankets and sweeping with sawdust and pushbroom are used to minimize the dissemination of dust and have proved beneficial in preventing the spread of respiratory infections.

Salicylates apparently do not protect a sensitized person from recurrences nor are they of much benefit in the treatment of recurrences, except for their antipyretic and analgesic effect. The administration of sulfanilamide once a hemolytic streptococcic infection has started has not prevented rheumatic recrudescences (Coburn,[24] 1944). The daily administraion of sulfathiazole or sulfadiazine throughout the year will reduce the incidence of streptococcic infection 80 per cent (Coburn,[24] 1944). A well controlled prophylaxis program is necessary to establish conclusively the advantages and disadvantages of such a procedure, which may involve serious hazards, and probably increases the number of patients who develop the poststreptococcal syndrome.

The use of penicillin in a prophylactic program, especially penicillin in pastilles for the prevention of the streptococcic infections, is now feasible. The employment of penicillin therapy for the acute hemolytic streptococcic infections of the throat does not tend to influence the rate of occurrence of recrudescence of rheumatic fever.

Reconditioning.—The purpose of reconditioning is threefold: first, to increase the blood circulation in the vital organs and thus promote oxygenation of the tissues; second, to prevent the development of muscular weakness, and third, to maintain interest and morale. A reconditioning program should begin as soon as the patient is well enough to cooperate in supervised deep breathing exercises. The Goldthwait breathing exercises are used. Deep breathing exercises are followed by muscle extension and flexion exercises in bed. When the patient has reached the inactive stage of the disease graduated exercises should be prescribed so that fatigue may be prevented and muscle tone maintained.

Educational Program.—As soon as the patient is comfortable, diversional reading is begun, followed by studies within the patient's field of interest. By occupational, educational and reconditioning programs the patient's morale is maintained, recovery is hastened and fewer psychoneurotic traits develop.

SUMMARY

In this overall survey of a large group of rheumatic fever patients of military age the following observations deserve further emphasis:

1. Rheumatic fever definitely followed epidemics of the streptococcic throat infections.

2. The sulfonamide method of treatment of the streptococcic throat infections did not prevent the development of the poststreptococcic rheumatic syndrome.

3. The largest number of the rheumatic fever patients of military age fell into the subacute monocyclic type, 61.3 per cent, and the frequency of carditis in this group emphasizes its importance in relation to the development of chronic valvular heart disease.

4. Pneumonitis is second to carditis in importance because of its frequency, its relation to primary right sided heart failure and as a cause of death.

5. Every patient with a streptococcic throat infection is a potential rheumatic fever subject and the early recognition of the poststreptococcic rheumatic syndrome and the institution of adequate early salicylate therapy is paramount.

ATYPICAL FEATURES OF RHEUMATIC FEVER IN YOUNG ADULTS

MAURICE SOKOLOW, M.D.
San Francisco
and
ALBERT M. SNELL, M.D.
Rochester, Minn.

Rheumatic fever has been described so often and so well that the classic variety of the disease is universally recognized and promptly diagnosed, even by those whose experience in the field has not been large. That atypical forms of the acute phase of the disease exist and pass unrecognized is, however, well demonstrated by the frequent finding of late valvular disease among patients who give no history of an acute episode of fever or involvement of joints. In a large naval hospital where many patients with proved or suspected rheumatic fever were under observation, many of the atypical phases of the acute rheumatic state were seen and followed over considerable periods. It is the purpose of this paper to discuss some of the less well known clinical syndromes of rheumatic fever in the hope that such a report will assist others in the earlier diagnosis of similar cases.

CRITERIA FOR DIAGNOSIS

Jones,[1] in a helpful paper, has discussed the criteria for the diagnosis of rheumatic fever. He has divided the clinical manifestations into: (1) major manifestations (carditis, arthralgia, chorea, nodules and verified history of previous rheumatic fever) and (2) minor manifestations (fever, abdominal or precordial pain, erythema marginatum, epistaxis, pulmonary changes and abnormal laboratory findings). He has suggested that any combination of the major manifestations or the presence of one major and two minor manifestations of the disease gives one a reasonably certain basis for diagnosis. We have attempted to use these criteria as a working plan in our cases but have encountered some difficulty in depending on them entirely. Chorea and subcutaneous nodules were only rarely present in our adult cases and so were of limited diagnostic value. A history compatible with previous rheumatic fever was present in approximately a third of our cases, but if one had insisted on a medically verified history the percentage would have been considerably lower. Cardiac enlargement, pericarditis, congestive failure and significant cardiac murmurs were infrequent at the time of admission. These were present in less than 10 per cent, if one interprets a clinically significant cardiac murmur as being either a diastolic murmur or a long, loud systolic murmur not varying with respiration or position. Abnormalities in the electrocardiogram remained, therefore, as the principal reliance in the diagnosis of the rheumatic state. Prolongation of the PR interval and inverted T waves in lead 1, 2 or 4 constituted more than 90 per cent of the significant

changes noted. Slight deviations of the ST segment, ectopic beats and slight lowering of the T waves were not considered as clinically significant.

Arthralgia, with or without visible evidence of acute arthritis, was the most commonly encountered clinical symptom. Objective articular manifestations were often absent, although the subsequent course of the disease indicated that the subjective pains in the joints were significant of rheumatic disease. It became apparent that the only common major manifestations (according to the Jones criteria) were arthralgia or arthritis and abnormalities in the electrocardiographic pattern[1]. At times one or the other was absent, and under such circumstances the minor diagnostic criteria had of necessity to be utilized.

Of the minor manifestations, an elevated sedimentation rate and elevation of temperature were the most consistently helpful. It was extremely rare to see a patient with active rheumatic fever without elevation of temperature or with a normal sedimentation rate, although such negative findings were observed on occasion in cases in which carditis subsequently developed. The elevation of temperature was often of short duration whereas the sedimentation rate was usually the last sign of activity to disappear. The sedimentation rate was, therefore, of more practical value than elevation of temperature, especially if the disease was not encountered early in its course. Tachycardia was present usually only in the early stages, with fever (unless pericarditis or cardiac failure was present), and often the cardiac rate was normal despite other obvious signs of rheumatic activity, including carditis. Epistaxis, erythema marginatum, abdominal and precordial pain and pneumonitis were all observed but were sufficiently infrequent to be of little diagnostic aid in many cases. Anemia was surprisingly uncommon, considering its frequency in the rheumatic fever of childhood, but occasionally it was helpful in indicating the possibility of continued rheumatic activity rather than as an initial diagnostic aid. Leukocytosis was present in approximately two thirds of the cases observed by us but was usually of relatively short duration. The elevated sedimentation rate was, as has been previously stated, a more reliable and persistent sign than other minor manifestations.

The presence of a known streptococcic disease within the previous six to eight weeks was helpful in focusing attention on the possibility of rheumatic fever, and many mild rheumatic infections were detected by following the sedimentation rate and examining the electrocardiographic pattern. It was in this group of cases particularly that many of the atypical early clinical features of rheumatic fever were recognized.

Our experience, therefore, has indicated that arthralgia or arthritis, especially following a known streptococcic disease of the upper part of the respiratory tract, in association with significant abnormalities in the electrocardiogram, with fever and an elevated sedimentation rate, is the most common combination of symptoms and signs in young adults with rheumatic fever. The other major and minor manifestations, as outlined by Jones, were not sufficiently common in the present series of cases to be used as the sole possible criteria for a diagnosis.

CLINICAL MANIFESTATIONS

I. *Minimal Presence or Complete Absence of Articular Symptoms.*—The absence or insignificance of articular symptoms in rheumatic fever has frequently been described in the literature. This feature is relatively common in patients who have recently had a streptococcic infection, particularly scarlet fever. We have frequently observed patients convalescing from the last-mentioned disease or from an infection of the upper part of the respiratory tract who, because of failure to regain strength or because of vague arthralgia, were sent to the hospital for study. An abnormal electrocardiogram was demonstrated, and the patients subsequently were shown to have rheumatic fever. Some of these patients have had no articular symptoms whatever at any time; in others the symptoms referable to the joints were mild and entirely subjective. Nevertheless, active carditis was eventually demonstrated in certain of these patients.

The significance of these late poststreptococcic manifestations has been the subject of a number of recent reports.[2] These papers have indicated that after scarlet fever or streptococcic pharyngitis approximately 15 to 20 per cent of adults will show clinical or electrocardiographic manifestations indistinguishable from those of rheumatic fever. In the patients described by these observers one group had classic rheumatic fever, while another group had vague arthralgia, feelings of ill health and mild secondary rises of temperature. These symptoms were often so mild that a physician would hardly have been consulted. A third group remained completely asymptomatic; yet laboratory and electrocardiographic findings developed which were similar in all respects to those of the group that had frank rheumatic fever. These observations as well as our own strongly suggest that rheumatic fever following streptococcic diseases varies quantitatively in a striking manner and may present itself with protean manifestations ranging from a clinically silent to a clinically fulminant disease. On the basis of our own experience, the importance of care- [illegible] eptococcic symptoms with the [illegible] fever in mind can hardly be overestimated.

II. *Monarticular Involvement.*—The classic feature of rheumatic fever is a migratory polyarthritis. It must, however, be emphasized that in many cases rheumatic fever may show monarticular involvement throughout its entire course or for a period before the typical polyarthritic spread occurs. Recent articles from the military services have noted this feature.[3]

Our experience has been that the joints of the lower extremities were those most commonly involved. The frequency of monarticular involvement of the ankles, the small joints of the feet and the knees probably was responsible for erroneous diagnoses of sprained ankle, flat feet or sprained knee which were initially often made in these cases. When an injury does not seem to be the obvious explanation for pain and swelling in a single joint of the lower extremities, it is necessary to consider the possibility of rheumatic fever.

III. *Onset and Major Manifestations in Hands and Feet.*—It is not often appreciated that involvement of the small joints of the hands and feet may dominate the clinical picture of rheumatic fever and often may be the sole articular manifestation of the disease. The following report of a case demonstrates this fact and emphasizes that a careful study of the aspects of the disease other than articular may reveal the significance of unusual symptoms referable to the joints.

CASE 1.—A man aged 18, who had severe febrile pharyngitis on March 5, 1945, was treated with sulfadiazine and was returned to duty four days later without residual symptoms. He was transferred to a new station and there reported to the sick bay on April 10, complaining of swelling and stiffness of the interphalangeal joints of the index and middle finger of each hand, of twenty-four hours' duration. It was observed that he had a temperature of 100 F. and that his hands were swollen and slightly tender, with pain on active and passive motion of the affected joints. The sedimentation rate was 25 mm. in one hour (Westergren). A tentative diagnosis of rheumatic fever was made, and the patient was transferred to a naval hospital two days later. On arrival his joints were apparently normal except for slight tenderness on manipulation of the joints that had been so painful and swollen forty-eight hours before. A faint maculopapular rash was present over his thorax, abdomen, hips and thighs. There was a soft apical systolic murmur.

The laboratory data revealed normal results of urinalysis, a hemoglobin content of 87 per cent, a leukocyte count of 9,200 per cubic millimeter of blood, a negative Kahn reaction and a sedimentation rate of 29 mm. in one hour (Westergren method). The vital capacity was 4.2 liters. The electrocardiogram revealed partial heart block, with a PR interval of 0.28 second.

The patient was given routine treatment with rest in bed and 10 Gm. of salicylates daily, the doses being administered every four hours. At no time did he have further pains in the joints, and he was afebrile and asymptomatic throughout his stay in the hospital. The partial heart block was still present on April 15 (PR interval 0.32 second), but had disappeared by April 27 (PR interval 0.19 second). The T waves were upright in all leads. The sedimentation rate gradually fell from a level of 28 mm. per hour on April 17 to one of 7 mm. per hour on May 18.

It is apparent that this patient had rheumatic fever with involvement of the interphalangeal joints of each hand as the only articular manifestation of the disease. The articular symptoms lasted only forty-eight hours, but a prolonged PR interval was observed at a time when the joints were normal to physical examination. The sedimentation rate became normal after almost a month, being the last sign of rheumatic activity to disappear. It is to be noted that the leukocyte count was normal when other definite signs of activity were present.

IV. *Prodromal Aching for Days to Weeks Prior to Onset of Acute Arthritis.*—Rheumatic fever is usually thought to be a disease in which the articular symptoms appear rather abruptly and are acute. Nevertheless, fleeting but recurrent mild polyarthralgia without objective signs may precede the usual type of involvement of the joints. As the following report of a case indicates, polyarthralgia (even in the absence of objective involvement of the joints) subsequent to a known streptococcic respiratory infection should indicate the necessity for further study.

CASE 2.—A man aged 18 had a long-lasting febrile infection of the upper part of the respiratory tract in February 1945 and was hospitalized for a month. He had a residual cervical adenopathy but was otherwise well until about the middle of April, when he noted aching pain in the feet. He reported to his local sick bay where a physical examination was reported as negative and the sedimentation rate as 14 mm. in one hour. He was given sulfonamide drugs and salicylate preparations and assigned to light duty. The aching became milder, and he returned to full duty after a few days even though slight residual symptoms persisted. A week later he again reported to sick bay because of continued aching in the back in addition to the pain in the feet. The sedimentation rate at this time was reported as 27 mm. in one hour. After he had been kept under observation in the sick bay for several days, aching appeared in his toes. Objective findings were not observed although the pain in his joints became migratory in type. On the day before entry to a naval hospital (May 16) redness, pain and swelling developed in the toes of both feet, and in the evening he noted similar changes in both ankles.

On arrival at the hospital his only complaints were referable to his toes, the pain in the ankles having practically subsided. The right great toe was slightly red, swollen and extremely tender. The ankles were tender on pressure but were not badly swollen. The patient had a temperature of 103 F. and a pulse rate of 100. The heart was not enlarged, but there were a slight, soft apical systolic murmur and a diastolic gallop rhythm. The laboratory data revealed a normal urine, a hemoglobin content of 78 per cent, an erythrocyte count of 3,900,000 and a leukocyte count of 11,500 per cubic millimeter of blood with 75 per cent polymorphonuclear cells. The blood culture was negative on two occasions; the Kahn reaction was negative and the sedimentation rate was 28 mm. in one hour. The electrocardiogram on entry showed a PR interval of 0.28 second with a Wenckebach phenomenon and dropped beats (fig. 1).

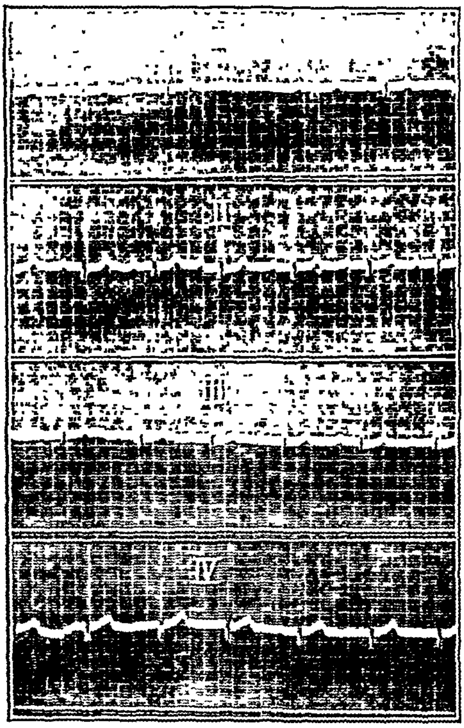

Fig. 1 (case 2).—Partial auriculoventricular block with Wenckebach phenomenon (lead 1).

The patient was put to bed and full doses of salicylates were administered. The temperature fell rapidly, being 100.4 F. on May 18 and normal thereafter. The sedimentation rate fell gradually, no significant change being noted for two weeks, but by June 25 it had fallen to 5 mm. in one hour. The partial heart block persisted until June 11; it was noteworthy that for weeks the PR interval was 0.24 to 0.28 second with cardiac rates in the sixties without dropped beats. On June 25 there appeared a short, rough aortic systolic murmur, grade 2 (on the basis of 1 to 4, in which 1 indicates the mildest and 4 the most severe condition). Administration of salicylates was continued until the patient's transfer to a convalescent hospital on July 24, at which time his electrocardiogram was normal and his sedimentation rate varied from 5 to 10 mm. in one hour.

Case 2 illustrates that rheumatic fever may be initiated by migratory aching and stiffness of several joints lasting days to weeks before fever, acute polyarthritis and carditis appear. The interpretation of polyarthralgia as an isolated clinical feature is often difficult, but an elevated blood sedimentation rate and a previous history of an infection of the upper part of the respiratory tract should have suggested the diagnosis in this case. The myocardial and valvular damage that eventually resulted might have been prevented by earlier diagnosis and treatment. The apical diastolic gallop was the earliest clinical sign of carditis in this case, although later a significant aortic murmur appeared.

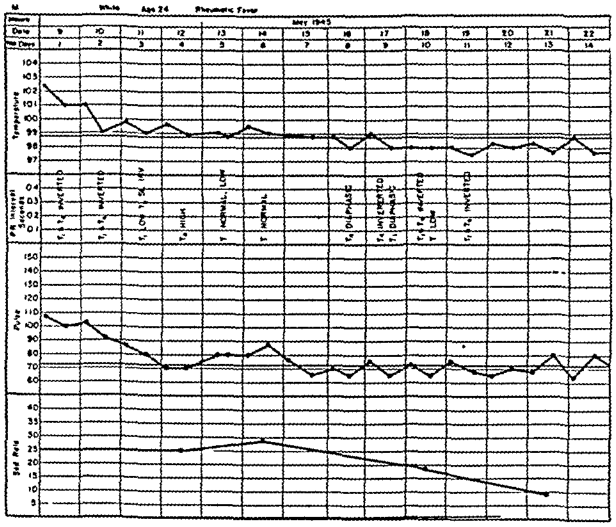

Fig. 2.—Typical temperature chart in rheumatic fever treated with salicylates.

V. *Recurrent Acute Arthritis of Short Duration With Apparently Complete Subsidence Between Attacks.*—Polycyclic rheumatic fever is a well recognized variety of the disease, but in the typical cases each cycle represents fairly classic features of rheumatic fever of significant duration. We have observed a number of cases in which apparently complete relief of acute arthritis and fever and reduction of the sedimentation rate occurred in a few days on relatively small doses of salicylates. It was not until this type of episode was repeated several times, often with a different group of joints involved in each attack, that the patient in question was referred to a hospital for study. In most of our cases of this type the recurring arthritis reappeared in a few days, often within a week after the patient had been returned to duty.

Case 3.—A man aged 25 was admitted to a naval hospital on April 3, 1945 with a diagnosis of acute arthritis. He had had a sore throat on several occasions in the past two years, the last time on Feb. 15, 1945. On March 10 aching pain without swelling had developed in the right knee. He continued ambulant, but a week later the pain was severe and definite swelling had appeared. He reported to his sick bay, where it was noted that his right knee was swollen, red, hot and tender. The sedimentation rate was 25 mm. in one hour and the temperature 100.2 F. He was put to bed with hot packs and given 3 Gm. of salicylates daily. He became afebrile in five days and the joint symptoms subsided within a week. The sedimentation rate was 10 mm. in one hour on March 26. No electrocardiographic study was done at this time. He was returned to duty on March 29. Within forty-eight hours pain and swelling in the right knee had reappeared, and the next day the left knee was similarly affected.

On arrival at the naval hospital examination revealed a temperature of 100 F. and slight swelling and tenderness of both knees. Examination of the heart gave essentially negative results. Laboratory studies revealed moderate anemia; the sedimentation rate was 25 mm. in one hour and the electrocardiogram was normal.

Salicylates, 10 Gm. daily, were administered and strict rest in bed was ordered. The patient was afebrile within twenty-four hours and the arthritis was completely quiescent within a week. Serial electrocardiograms taken twice weekly for two months showed no abnormalities. The sedimentation rate fell gradually, serial determinations twice a week being 18, 15, 13, 11, 12, 10, 14, 13 and finally 5 mm. per hour on May 21, seven weeks after entry.

On May 22 subcutaneous nodules about the knees were noted, and on full range of motion his knees were slightly painful. The patient was still taking salicylates. He felt "washed out" and was easily fatigued on the slightest exertion. At this period an early aortic diastolic murmur appeared. The sedimentation rate remained normal, being 5 and 6 mm. per hour on subsequent determinations. The diastolic murmur persisted, and shortly thereafter the patient was transferred to a convalescent hospital.

Case 3 illustrates (1) monarticular involvement; (2) rapidity of recurrence with premature physical activity; (3) the need for clinical as well as laboratory study, since electrocardiographic tracings were normal and yet a diastolic murmur developed while the patient was under observation, and (4) the presence of rheumatic activity despite a normal blood sedimentation rate.

VI. *Absence of Fever During the Acute Stage.*—Fever is almost invariably present in the acute rheumatic state, but we have observed several cases in which temperatures were never elevated during the period of observation. It is of course possible that fever had been present prior to hospitalization. As a general rule, fever subsided promptly (within four or five days) on full doses of salicylates and rest in bed, but it is not likely to do so while the patient is ambulatory.

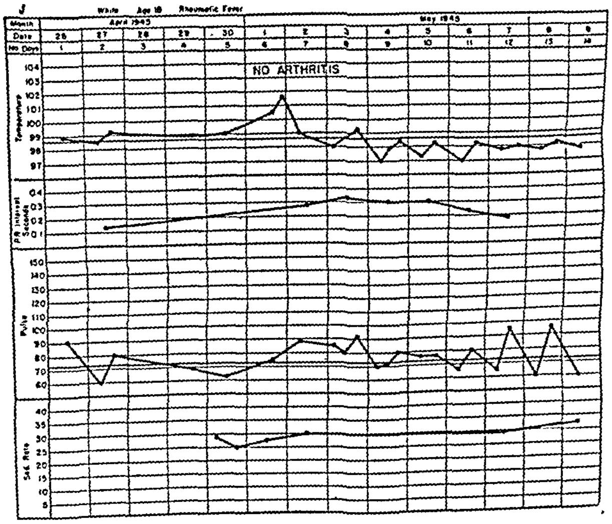

Fig. 3.—Subclinical polycyclic episode. The patient was unaware of fever.

VII. *Atypical Febrile Course in the Observative State.*—Rheumatic fever is not often considered in the differential diagnosis of pyrexia of unknown origin, and it is uncommon for fever to persist as the sole clinical evidence of rheumatic activity. Characteristic temperature charts in rheumatic fever are illustrated in figures 2 and 3. The fever when present is often remittent, and the daily swings usually vary between 1 and 3 F. Wide swings usually indicate the presence of some other disease. A few cases of chronic active rheumatic fever may show a low grade rise of temperature for weeks, and subclinical reactivations may cause secondary fever of short duration (fig. 3), but the fever of the acute phase subsides rapidly. When fever was high or prolonged in our cases pericarditis was usually present (figs. 4 and 5, see also case 7).

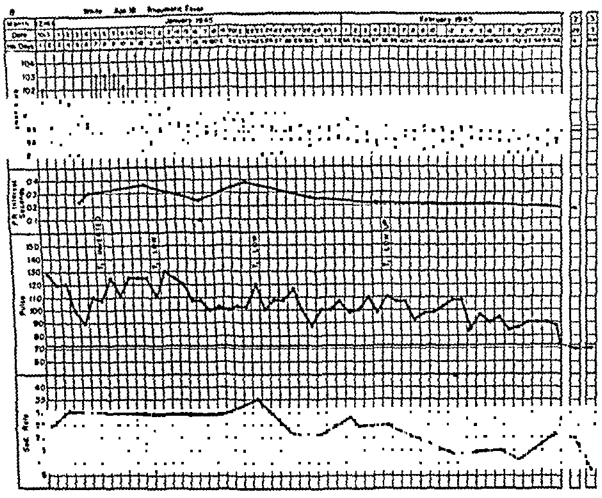

Fig. 4.—Course of rheumatic fever with acute pericarditis.

Case 4 illustrates the difficulty of diagnosis when articular symptoms are late in appearing and the febrile course is atypical.

Case 4.—A Negro man aged 19 was admitted to a naval hospital on April 12, 1945. He first had become sick aboard ship on March 2, with headache and a temperature of 103 F. No abnormalities were found on examination, and he had no localizing symptoms. He was given sulfadiazine and penicillin, but the fever persisted. The blood count, urinalysis, blood serum agglutinations and stool cultures were normal. On March 7, five days later, he complained of severe pain in his groins on weight bearing, with tenderness along his adductor muscles. On March 10 his temperature was still variable, between 100 and 102 F., and pain and swelling developed in the metacarpophalangeal joint of the middle finger of the right hand. The pain in his groin, which was presumably due to involvement of his hip joints, had disappeared. The sedimentation rate was 26 mm. in one hour. On March 20, eighteen days after the onset of his fever, he noted redness, swelling and pain in the right wrist. The left wrist, both elbows and the knees were sore but not swollen. The diagnosis of rheumatic fever was made, salicylate therapy was begun and he was transferred to the United States.

On arrival the patient had taken no salicylates for six days. The pains in his joints, which had rapidly subsided with full doses of salicylates, had partially recurred, and he complained of aching and stiffness in his right wrist and elbow. On examination he was afebrile. Examination of the heart gave negative results. The sedimentation rate was 25 mm. in one hour. The electrocardiogram revealed a sinus tachycardia of 126 per minute and a PR interval of 0.22 second. The T waves in leads 1, 2 and 4 were low or diphasic.

The patient was put to bed and given 10 Gm. of salicylates daily. His symptoms cleared rapidly and completely. Sedimentation rates taken twice weekly fell rapidly to normal, the figures being 25, 19, 26, 17, 15, 9, 9 and 7 mm. in one hour on May 8, 1945, less than a month after admission. Another electrocardiogram taken on April 26, two weeks after entry, revealed a PR interval of 0.17 second with a cardiac rate of 90; the T waves in leads 1, 2 and 4 were taller than before but still abnormal. On May 3, three weeks after entry, the PR was 0.16 second and the T waves were normally upright. The patient was allowed up on May 10, 1945 and had no recurrence of symptoms or signs of activity of rheumatic fever.

Case 4 illustrates the diagnostic problem of fever without localizing symptoms which would point to rheumatic fever. The first pain in the joints occurred five days after the onset of fever, but the pain in the groin was not recognized as being related to the involvement of joints. A single finger joint then was involved a few days later, but this symptom subsided quickly. It was not until eighteen days after the onset of the fever that polyarthritis developed and clarified the diagnosis. Electrocardiographic studies might have permitted an earlier recognition of the disease.

VIII. *Association of Rheumatic Fever and Marie-Strümpell Spondylitis.*—It is believed by some observers that Marie-Strümpell spondylitis is a variety of rheumatoid arthritis although a distinct and separate disease. The exact relationship between rheumatoid arthritis and rheumatic fever is not clearly established, and renewed interest has been shown recently in the cardiac observations in the first-named condition. When one sees patients in whom both diseases are present, the concurrence emphasizes the entire problem. We have observed 6 such cases, of which the following is an example.

Case 5.—A man aged 19 had pain in both feet, ankles and the lower part of the back on Oct. 5, 1945. On salicylate therapy, the ankles improved but his back and feet remained painful. Progressive involvement, despite salicylate therapy, appeared in the knees, shoulder and hips, and these joints were still painful at the time of his arrival at a naval hospital on Nov. 30, 1945. He had lost 15 pounds (6.8 Kg.) and had considerable stiffness of the neck and back in addition to the pain in his peripheral joints.

Examination revealed decided limitation of motion and spasm of muscles in the lower part of the back. The heart was not enlarged, but there was a moderately loud, low-pitched mid-diastolic murmur at the apex. There was also an apical systolic murmur, grade 2. No definite aortic valvular murmurs were heard. To judge from the patient's health record, these murmurs had not previously been present. The sedimentation rate was 27 mm. in one hour. The electrocardiogram was normal. Roentgenographic examination of the sacroiliac joints revealed changes characteristic of spondylitis (fig. 6).

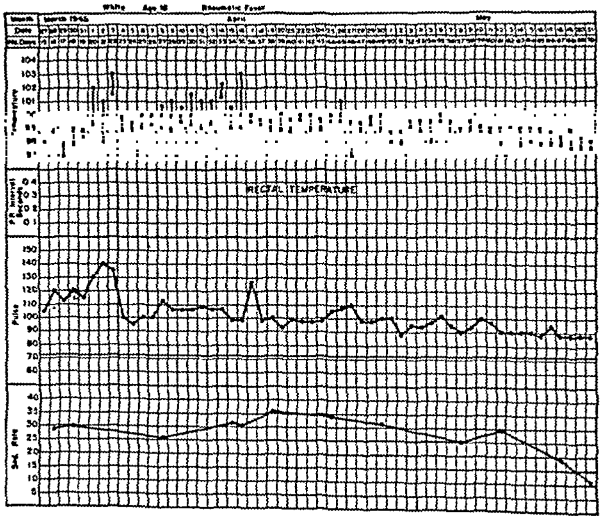

Fig. 5.—Course of rheumatic fever with acute pericarditis.

Despite large doses of salicylates, the patient continued to have an elevated sedimentation rate and pains and stiffness in the neck, back, hips and feet, while the electrocardiogram remained normal over a *four months period* of observation.

The expansion of the chest decreased over a six months period from 2½ inches (6.4 cm.) to 1 inch (2.5 cm.). On Dec. 13, 1945 an early aortic diastolic murmur was heard for the first time, to the left of the sternum in the third interspace. This murmur was transient, and on March 16, 1946 only the mid-diastolic apical rumble was heard.

Case 5 is a rare and interesting example of the coexistence of salicylate-resistant chronic arthritis, of spondylitis proved by the well known roentgenographic findings and of mitral valvulitis and transient aortic insufficiency. This case was the only one observed in which active rheumatoid arthritis and spondylitis coexisted with active carditis and valvulitis and changing murmurs.

IX. *Abdominal and Precordial Pain as the Initial Manifestation.*—Abdominal and precordial pain has frequently been said to dominate the clinical picture in some children with rheumatic fever. In adults, however, these symptoms are usually not prominent and are difficult to evaluate when present. Precordial pain was more commonly present than was abdominal pain in our cases but rarely appeared as the sole symptom. One patient, subsequently shown to have rheumatic fever, had three distinct episodes of abdominal pain and fever of forty-eight hours' duration over a seven week period before typical polyarthritis and carditis appeared.

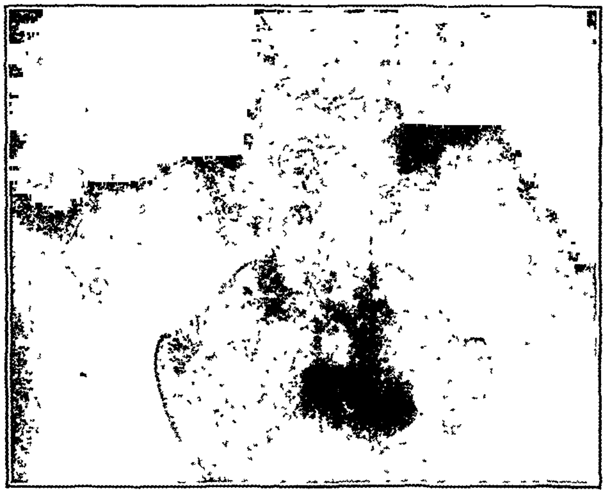

Fig. 6 (case 5).—Sacroiliac arthritis in a patient with rheumatic fever.

X. *Onset with Pericarditis and Pneumonitis.*—While rheumatic fever is classically associated with the development of pancarditis, pericarditis is usually not clinically recognizable in most cases, the arthritis and myocardial involvement being most prominent. However, occasionally pericarditis is the dominant clinical feature. Rheumatic pneumonitis has been discussed by recent authors and experience in the armed services has indicated that it is more frequent than formerly was thought. Griffith[4] stated that pneumonitis occurred in 12 per cent of his cases. We believe this figure to be rather high, 2 per cent being about the incidence among the patients observed by us.

Case 6.—A married woman aged 29 entered a naval hospital on July 20, 1944, complaining of chills and fever, of pain in the right upper portion of the thorax on breathing and of vomiting of forty-eight hours' duration. Her past history was uneventful. Examination revealed a temperature of 101.8 F., a pulse rate of 118, and a respiratory rate of 24. The pertinent observations were moderate inflammation of the pharynx, slight generalized tenderness over the abdomen and decreased breath sounds over the right anterior portion of the thorax with a friction rub over the same area. The laboratory data revealed normal urine, a leukocyte count of 21,650 per cubic millimeter of blood, with 72 per cent polymorphonuclear cells, a hemoglobin content of 12 Gm. per hundred cubic centimeters of blood and an erythrocyte count of 4,000,000 per cubic millimeter of blood. The diagnosis on admission was pneumonia and pleurisy. On the second day in the hospital the patient complained of pain across the upper part of the thorax; the fever was unchanged in spite of full doses of sulfadiazine. Roentgenologic examination of the thorax revealed a widened cardiac silhouette with bilateral pleural effusion. Five days after entry, examination revealed muffled heart sounds and a definite pericardial friction rub. Detailed questioning elicited the fact that for several days she had had migratory aching pain in several joints. She did not spontaneously mention these pains.

Therapy with sodium salicylate was begun on July 25. The pericardial friction rub persisted until August 3; the fever rapidly decreased, and by August 7 the temperature was normal. The pleural effusion and pneumonitis rapidly cleared, and the roentgenologic examination of her thorax gave negative results on August 4, except for the enlarged heart shadow. A transient apical systolic murmur, grade 2, became audible in the second week.

An electrocardiogram on July 25 revealed inverted T waves in all leads. These had become normal by August 29. The auriculoventricular conduction time was consistently normal. The sedimentation rate, which was 25 mm. in one hour on entry, persisted at the level of 25 to 35 mm. and slowly diminished until August 29, when it was 7 mm. The patient was then sent home for further convalescence. She was seen again on September 20, when she complained of tightness in her thorax. The electrocardiogram was normal, but the sedimentation rate had increased to 13 mm. in one hour. The heart was normal except for moderate enlargement. She was seen again on Oct. 23, 1944, at which time she made no complaints. Roentgenologic examination showed that the heart and the lungs were essentially normal. The electrocardiogram was normal and the sedimentation rate was 15 mm. in one hour.

Case 6 illustrates the onset of rheumatic fever with pleurisy, pneumonia and pericarditis. Articular findings were absent, and a history of articular pain was elicited only on questioning. The cardiac enlargement and pericardial friction rub provided the evidence which led to the final diagnosis.

Case 7.—A man aged 20 was admitted to the hospital on June 29, 1945 for a submucous resection of the nasal septum. Four days after surgical intervention he had symptoms and signs of acute tonsillitis and sinusitis with a temperature of 103 F. He responded promptly to treatment and was returned to duty. Over the next few days there developed feverishness and substernal pain brought on by leaning forward. On July 16, 1945 the patient was readmitted to the hospital, where physical examination revealed an acutely ill man with fever, tachycardia, pharyngitis and distended cervical veins. The heart was enlarged, and a diastolic gallop and a precordial friction rub were heard. The blood pressure was 114 mm. of mercury systolic and 76 diastolic. Urinalysis was negative. The leukocytes numbered 12,000 per cubic millimeter of blood with 80 per cent polymorphonuclear cells. The sedimentation rate was 25 mm. in one hour. The venous pressure taken in the cubital vein was 20 cm. of water. The throat culture revealed many hemolytic streptococci. The electrocardiogram showed a PR interval of 0.26 second, elevated ST segments in leads 1, 2 and 4, a low T wave in lead 1 and diphasic T waves in leads 2 and 3. The blood culture was negative.

The patient was placed in an oxygen tent and given full doses of salicylates and large doses of penicillin (40,000 units every two hours intramuscularly). His condition continued to be critical for a week. The precordial friction rub was heard daily until July 26. The venous pressure varied between 16 and 20 cm. of water. Roentgenographic examination of the thorax on July 22, 1945 revealed an "enlarged and bulging cardiac silhouette" (fig. 7). The T waves in leads 1, 2 and 4 became inverted; the auriculoventricular block and inverted T waves persisted, and an intraventricular block appeared. At no time did the patient have subjective or objective manifestations of articular involvement. On July 29 an aortic diastolic murmur was heard and a pleural rub appeared in the left axilla, associated with pain on cough and deep respiration. This persisted for several days and gradually subsided. On August 13 pain without visible swelling appeared in the knees and elbows. This persisted for only four days. The improvement of the patient continued progressively, and by August 28 the auriculoventricular conduction had returned to normal although the T waves were still inverted. The sedimentation rate was 18 mm. per hour at this time. The aortic diastolic murmur persisted, but the cardiac shadow gradually decreased in size. The electrocardiogram became normal on September 21, approximately two months after admission. On October 12 the sedimentation rate was 12 mm. in one hour. On November 1 when the patient was transferred to a convalescent hospital roentgenographic examination of the thorax showed slightly generalized cardiac enlargement with normal pulmonary fields. The aortic diastolic murmur was still present.

---

[4] Griffith, G. C.: Rheumatic Fever: Its Recognition, California & West. Med. 63: 119-123 (Sept.) 1945.

This most instructive case illustrates the onset of rheumatic fever with pericarditis and pneumonitis. The late transient arthralgia, the persistent aortic diastolic murmur and the classic conduction defects and changes in the T waves confirmed the diagnosis.

XI. *Subclinical Recrudescence.*—The initial diagnosis of rheumatic fever is no more important than the recognition of recrudescence of activity in patients during convalescence or during an inactive period. The cases reported in this paper have illustrated that the rheumatic state manifests itself in different patients in different ways. Fever, elevation of the sedimentation rate, the appearance or reappearance of abnormal electrocardiographic tracings and articular symptoms or signs, all may be present singly or in combination—either in the initial attack or in the recrudescence. In order to observe the earliest evidence of recrudescence it is important to search for all these abnormalities when a patient is first allowed to resume physical activity. No patient should be allowed more than the slightest exertion until all signs of activity (fever, elevated sedimentation rate, pains of joints, rash, nodules, electrocardiographic changes and so forth) have subsided or until further observation reveals that the residual symptoms and signs are nonspecific.

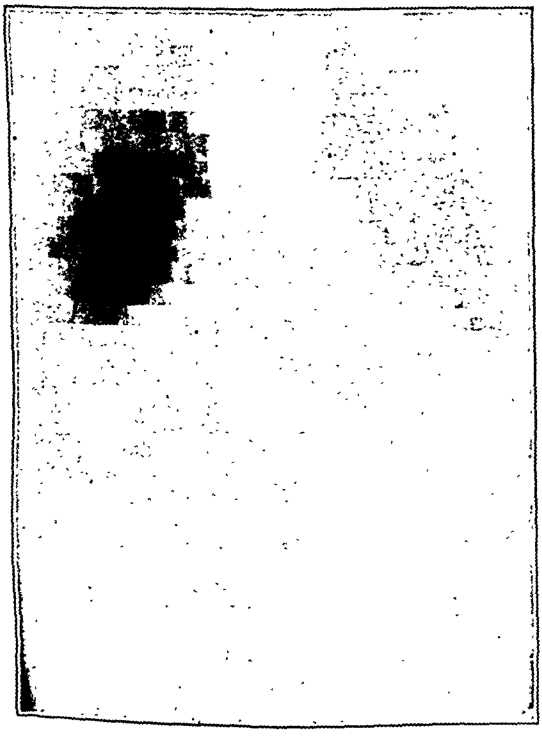

Fig. 7 (case 7).—Cardiac kymogram showing an enlarged and bulging cardiac silhouette and absent cardiac pulsations, typical of acute pericarditis.

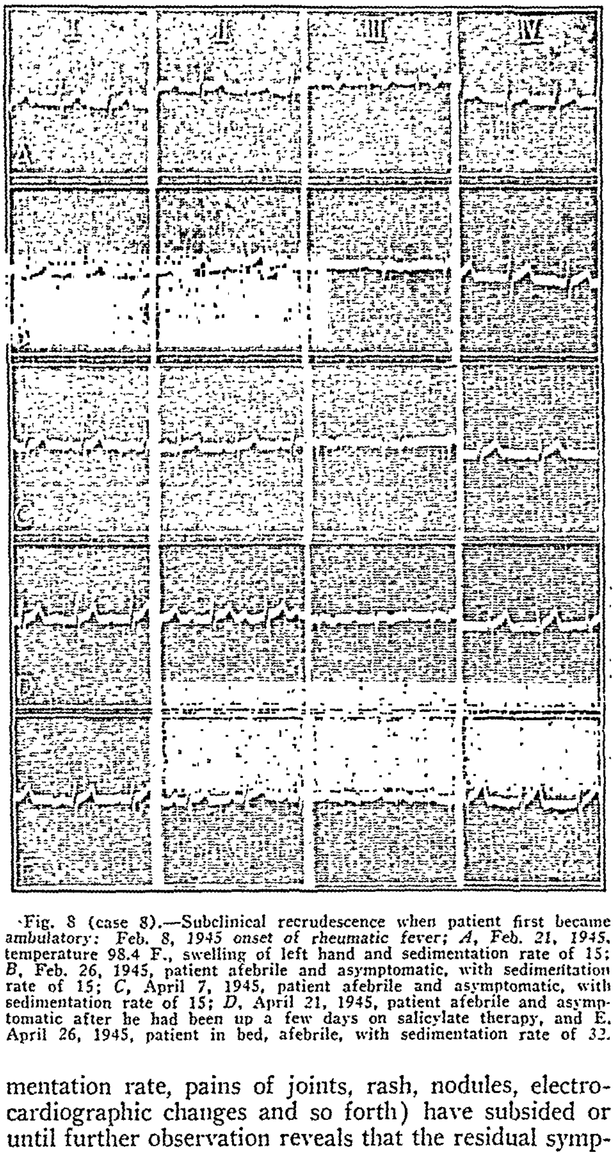

Fig. 8 (case 8).—Subclinical recrudescence when patient first became ambulatory: Feb. 8, 1945 *onset of rheumatic fever; A,* Feb. 21, 1945, temperature 98.4 F., swelling of left hand and sedimentation rate of 15; *B,* Feb. 26, 1945, patient afebrile and asymptomatic, with sedimentation rate of 15; *C,* April 7, 1945, patient afebrile and asymptomatic, with sedimentation rate of 15; *D,* April 21, 1945, patient afebrile and asymptomatic after he had been up a few days on salicylate therapy, and *E,* April 26, 1945, patient in bed, afebrile, with sedimentation rate of 32.

CASE 8.—A man aged 18 had arrived on the west coast on Jan. 16, 1945. A cold had developed on his arrival. He stood watches in the rain and noticed pain in the heels while walking. This pain increased, and a week later he was examined but no abnormalities were noted. He was returned to duty, and on February 8 pain and numbness developed in his right hand. On examination his hand was found to be swollen. He was referred to a naval hospital on February 11.

On arrival it was further elicited that the patient had had occasional aching in his knees and shoulders during the previous ten days, but that pains in his heels and his right hand were most disturbing. He had had scarlet fever in childhood and mastoiditis in 1941.

Examination revealed pain and slight swelling and tenderness of the right metacarpophalangeal joints. The temperature was 98.4 F., the pulse rate was 80, the blood pressure was 132 mm. of mercury systolic and 84 diastolic. The heart was normal, there were no nodules and no rash was present.

The patient was put to bed and given full doses of salicylates. He was afebrile throughout. On February 13, within forty-eight hours of entry, the swelling and most of the tenderness of the right hand had disappeared. A soft apical systolic murmur developed, and the heart sounds were muffled. The prothrombin time, after two months of daily administration of salicylates, was 89 per cent of normal. His only complaint throughout his illness, after the first forty-eight hours, was weakness.

On April 10, after nearly two months of rest in bed and salicylates, the patient was allowed to get up. His sedimentation rate at that time was 10 mm. in one hour and his electrocardiogram was normal. The administration of salicylates was continued, and he was kept under careful observation. By April 19, his sedimentation rate had risen to 21 mm. in one hour and his PR interval had increased to 0.32 second (fig. 8). He had no fever or joint symptoms and was completely unaware of the flare-up. He was returned to bed, and after five days his partial heart block had disappeared, while his sedimentation rate fell to 9 mm. in one hour within ten days. He remained in bed until the last of May and was then allowed up without further incident.

The flare-up of symptoms after the patient had been allowed to get up stresses the necessity of a careful clinical and laboratory control when the patient first becomes ambulatory. The short duration of the abnormalities of the sedimentation rate and electrocardiogram during the flare-up is noteworthy. The fact that when the disease finally was quiescent the sedimentation rate was 5 mm. in one hour suggests that even when an apparently normal sedimentation rate of 10 or 12 mm. per hour is found the patient should be further observed to see that the lowest level is reached before he is allowed up.

COMMENT

The most important fact noted from a study of our cases is that rheumatic fever may manifest itself and run a clinical course in ways not commonly recognized. Failure to regain complete health or the appearance of symptoms within six weeks of a hemolytic streptococcic infection may indicate the development of rheumatic fever. In our experience, the most valuable criteria for the diagnosis of rheumatic fever in such atypical cases are: (1) arthralgia, (2) evidences of carditis, especially abnormalities in the electrocardiogram, (3) fever and (4) persistent elevation of the sedimentation rate. If evidence suggesting the possibility of rheumatic fever presents itself, one should review the history carefully for pains of joints, dyspnea, palpitation and abdominal or precordial pain; careful, frequently repeated examinations of the heart for significant murmurs, friction rub, diastolic gallop or enlargement should be made, and examination for nodules or cutaneous eruptions should be carried out. Repeated determinations of sedimentation rates and electrocardiograms must be performed to enable one to interpret the significance of any illness during this period. Arthralgia, however mild, occurring after an infection of the upper part of the respiratory tract must be investigated with some thoroughness. Almost all patients subsequently shown to have rheumatic fever had an elevation in the blood sedimentation rates at the time the arthralgia was present. This point may help to separate the arthralgias due to rheumatic fever from those due to other causes. Furthermore, the cases of rheumatic fever in which arthralgia occurred without visible signs of arthritis showed a rapid and complete subsidence of the articular symptoms following rest in bed and salicylate therapy. Additional joints may become involved in the chronic active rheumatic fever group, but the picture of persistent arthralgia of a single joint or set of joints was not that seen in our cases of rheumatic fever.

Postscarlatinal nonsuppurative arthritis must be considered to be identical with rheumatic fever, and the more carefully such patients are studied the more frequently will clinical and electrocardiographic evidences of carditis be found which are indistinguishable from those observed in rheumatic fever.

It is apparent from the foregoing reports of cases that the classic clinical picture of rheumatic fever in young adults is often absent and the diagnosis can be made only after a correlation of all the available data. In all the cases that we have reported, carditis as manifested either by electrocardiographic abnormalities or by transient signific [illegible], or by both, was present at some stage of the disease, thus confirming the diagnosis. Many similar instances could have been presented, however, in which carditis did not develop but which were nevertheless probably cases of rheumatic fever. Carditis may not be demonstrated in certain patients with rheumatic fever because electrocardiographic abnormalities may be extremely transient or absent, even if early serial records are made. Further, carditis may be absent in some cases of rheumatic fever.[5] The usual clinical signs of carditis were somewhat infrequent in our group of cases. Diastolic gallop, diastolic murmurs and cardiac enlargement were occasionally noted but occurred in only a modest percentage of cases. Cardiac failure was rare. A systolic murmur may appear in any febrile illness and, with the exception of certain long, loud murmurs, is not sufficient clinical proof of active endocarditis. One must rely, therefore, on abnormalities in the electrocardiogram as the most common and useful confirmatory evidence of the presence of myocarditis in the rheumatic fever of young adults.

Response to salicylates in our cases was usually striking, but this has not been considered a reliable criterion for diagnosis because other types of arthritic pain may similarly be relieved by large doses of salicylates.

SUMMARY

1. Observation of a large number of young adults with rheumatic fever indicates clearly that rheumatic fever often manifests itself with atypical clinical features and clinical course.

2. Of the clinical features, the most striking have been: minimal or complete absence of articular symptoms, monarticular involvement, onset with major manifestations in the hands and feet, prodromal aching for days to weeks prior to the onset of acute arthritis, recurrent acute arthritis of short duration with apparently complete subsidence between attacks, absence of fever during the acute stage, onset with fever of obscure origin, association of rheumatic fever and Marie-Strümpell spondylitis, onset with pericarditis and pneumonitis and subclinical recrudescence.

3. The most valuable common criteria for the diagnosis of rheumatic fever in young adults have been (1) arthralgia, (2) evidences of carditis, especially abnormalities in the electrocardiogram, (3) fever and (4) persistent elevation of the sedimentation rate. Other major and minor manifestations of rheumatic fever, such as chorea, nodules, cardiac enlargement, cardiac failure, pericarditis, diastolic and significant systolic murmurs, abdominal and precordial pain, erythema marginatum, epistaxis and pulmonary changes, are much less common.

4. The diagnosis of carditis, the most important major manifestation, has depended largely on significant transient electrocardiographic changes, particularly partial auriculoventricular block and inverted T waves in

leads 1, 2 or 4, alone or in combination. Other objective evidences of carditis have been less frequently observed.

5. Continued fatigability, failure to convalesce completely, the continuance or reappearance of low grade fever or the development of arthralgia, however variable and mild, in the weeks following a hemolytic streptococcic respiratory infection, should lead one to suspect the possibility of rheumatic fever. If a patient exhibits these clinical manifestations an appropriate clinical and laboratory investigation should be carried out.

PARA-AMINOBENZOIC ACID THERAPY OF ROCKY MOUNTAIN SPOTTED FEVER

Outline of a Comprehensive Plan of Treatment With Report of Five Cases

SAMUEL F. RAVENEL, M.D.
Greensboro, N. C.

The name Rocky Mountain spotted fever is now obviously geographically incorrect, since this disease has been found in forty-seven of the forty-eight states. Ten years ago 70 per cent of the cases occurred in the Mountain and Pacific states, while in 1945 87 per cent were reported from the Central and Eastern states. Its incidence and importance to public health in the United States are shown by the occurrence of 400 to 560 cases with 90 to 137 deaths each year during the past decade. Formerly it was believed that the eastern variety of Rocky Mountain spotted fever was mild, but in 1944 the mortality in 61 cases from the Rocky Moutain states was 32 per cent and in 241 cases from the South Atlantic states, 25 per cent.

Because of the tremendous area over which the cases occur it is probable that few physicians are afforded the opportunity to treat many patients with Rocky Mountain spotted fever and thus to develop an adequate concept of its management. As a corollary, the treatment of this formidable disease may often be haphazard and unsystematic. This probability is suggested by the occurrence of 20 deaths from Rocky Mountain spotted fever scattered over 16 different counties of Virginia in 1945 and 11 deaths in 11 counties of North Carolina during 1946. The need for a systematic, comprehensive plan of treatment applicable to every case is obvious. Such a plan is presented in this paper.

In the early days the treatment of this disease was symptomatic, which simply enabled the patient to die or recover somewhat more comfortably. Unfortunately, the pathologic changes in the vascular system were so striking and so emphasized in pioneer studies that the dictum was laid down that the parenteral administration of fluids was hazardous. As recently as 1943 Topping[1] wrote ". . . an occasional patient will require an additional amount (of fluids) parenterally. This had perhaps better be given by hypodermoclysis rather than intravenously, as there is some clinical evidence that any intravenous therapy is contraindicated." Martin[2] concluded that "blood transfusions probably also are contraindicated because of the endarteritis. . . . However, if the anemia becomes marked, transfusions may be necessary."

For years some physicians who were forced to battle with this fearful disease each summer were accustomed to administer intravenous fluids and blood transfusions with great freedom and apparently with considerable success. The rationale of these measures was arrived at empirically and as a result of long experience. It seemed that these patients should be, and were, benefited by measures calculated to prevent and overcome the phenomena of dehydration, depletion, anemia and metabolic starvation, which appeared so regularly in this severe disease. Such clinical "battles" sometimes were waged for a month or more, and many desperately ill patients recovered, but the mortality over a period of years averaged about 25 per cent.

It was not until 1944 that the careful studies of Harrell, Venning and Wolff[3] revealed the pathologic physiology of Rocky Mountain spotted fever and explained why properly chosen intravenous supportive therapy was so beneficial. They showed that because of the widespread vascular lesions plus starvation there was a tremendous loss of circulating body fluids and protein, with lowering of the blood chlorides, elevation of the nonprotein nitrogen of the blood and potential or actual development of peripheral circulatory collapse. They suggested that supportive therapy should include adequate amounts of plasma and whole blood in addition to dextrose, salts, vitamins and amino acids and should be controlled by careful laboratory studies. Furthermore, they pointed out that because of the intranuclear location of rickettsias in this disease any therapeutic agent must pass through two cell membranes in order to reach the organisms. This explains, in the opinion of these authors, why Topping's immune rabbit serum[1] appears to be effective only in the first three days of the rash—before many parasites have become established in cells.

The sulfonamide compounds are not only useless but probably harmful in the treatment of this disease. Experimentally, sulfonamide-treated guinea pigs died sooner than the untreated controls.[4] Since the sulfonamide drugs and para-aminobenzoic acid are antagonistic in action, use of the former is contraindicated in patients treated with the latter.

Although rickettsias are reported to be sensitive to penicillin, this agent has proved useless in the treatment of Rocky Mountain spotted fever.

The experimental and clinical background for the use of para-aminobenzoic acid in the treatment of spotted fever dates from 1942. Snyder, Maier and Anderson[5] showed that its oral administration would reduce the mortality of experimental murine typhus in white mice, while Hamilton, Plotz and Smadel[6] found that it would inhibit the growth of both epidemic and murine typhus rickettsias in chick embryos. These investigators and others[7] considered that para-amino-

Biol. & Med. **60**: 115-117 (Oct.) 1945. (*b*) Z[illegible] r, J. C., and Murray, E. S.: Immunity [illegible] cid Therapy in Experimental Tsutsugam[illegible] 61 [illegible] (March) 1946.

benzoic acid interferes in some way with the proliferation of the rickettsial organisms within tissue cells—probably by increasing cellular metabolism. This inhibits the infecting organisms sufficiently to permit the development of a lasting immunity. This hypothesis also explains why para-aminobenzoic acid may be therapeutically effective even late in the course of Rocky Mountain spotted fever, when rickettsias have become not only intracellular but also intranuclear.

Yeomans, Snyder, Murray, Zarafonetis and Ecke [8] treated 20 cases of louse-borne human typhus with para-aminobenzoic acid, with 44 untreated patients as controls. They believed that the course of the disease was favorably modified if the patient was treated in the first week of illness. (In the light of present knowledge both the dosage and the concentration of the drug in the blood were probably too low.)

Anigstein and Bader [9] found para-aminobenzoic acid effective therapeutically in guinea pigs infected with Rocky Mountain spotted fever rickettsias. All the control animals died, while those fed 2 per cent para-aminobenzoic acid in the diet either escaped infection or recovered from it. Hamilton [10] reported that para-aminobenzoic acid inhibits the growth of spotted fever rickettsias in chick embryos to an even greater extent than it does the growth of typhus rickettsias. Rose, Duane and Fischel [11] treated a 46 year old woman suffering from moderately severe spotted fever with para-aminobenzoic acid. She recovered with great rapidity. Maroney and Davis [12] reported the dramatic recovery of a 3 year old child in whose case treatment with para-aminobenzoic acid was begun on the twelfth day of severe spotted fever.

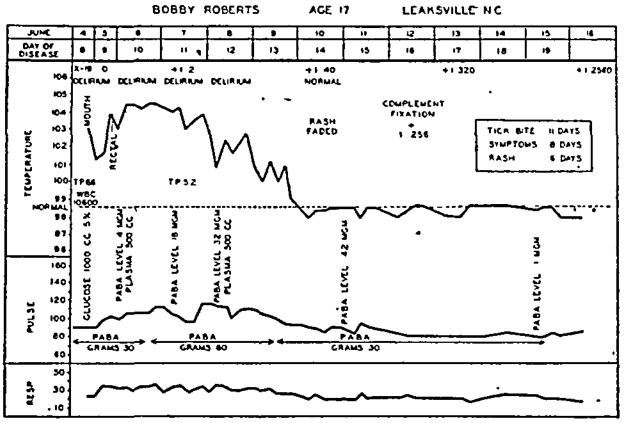

Chart 1 (case 1).—Para-aminobenzoic acid (PABA) therapy in severe case of Rocky Mountain spotted fever.

Murray, Zarafonetis and Snyder [7a] found that para-aminobenzoic acid protected 100 per cent of gerbils (small South African rodents) from multilethal doses of Rickettsia orientalis, the causative organism of tsugamushi disease (scrub typhus). Tierney [13] treated 18 cases of severe human tsutsugamushi disease with large doses of para-aminobenzoic acid. Blood levels of 30 to 60 mg. per hundred cubic centimeters were maintained. He concluded that para-aminobenzoic acid is an effective therapeutic agent in this disease.

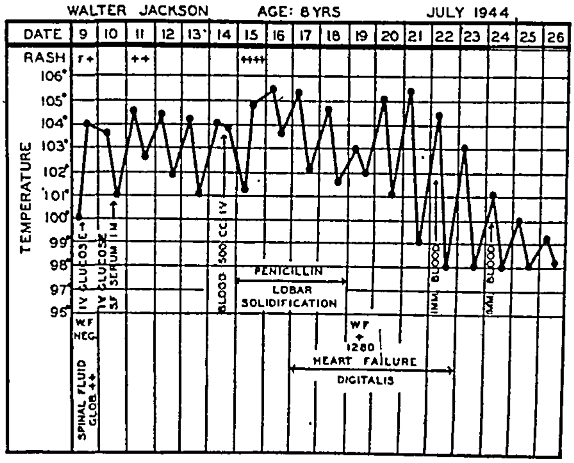

Chart 2 (W. J.).—Moderately severe case of Rocky Mountain spotted fever in 8 year old boy; treatment prior to para-aminobenzoic acid.

Smith [14] reported 29 patients with endemic typhus treated with moderate doses of para-aminobenzoic acid. In his opinion they recovered more rapidly than untreated control cases. (It is probable that better results would have been achieved with larger doses of the drug.)

REPORT OF CASES

Case 1.—*History.*—B. R., a white boy aged 17, entered St. Leo's Hospital June 4, 1946 with a history of tick bite, headache and malaise for eight days, fever and chills for seven days, rash for six days and delirium for two days before admission.

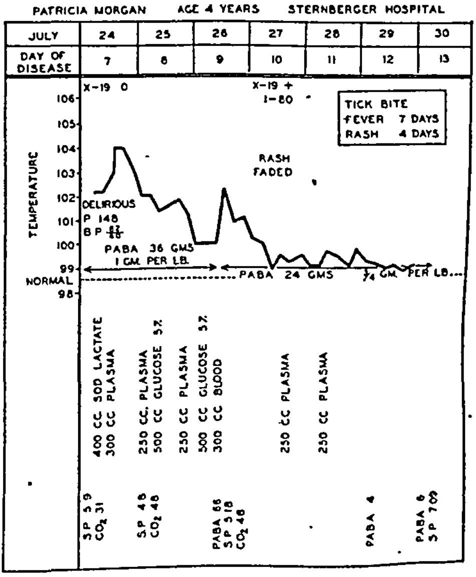

Chart 3 (case 2).—Para-aminobenzoic acid therapy in severe case of Rocky Mountain spotted fever.

Physical Examination.—Examination revealed a delirious, dehydrated boy with the classic hemorrhagic rash of Rocky Mountain spotted fever, conjunctivitis, palatal enanthem and slight scrotal edema. The serum protein concentration was 6.6 Gm. per hundred cubic centimeters.

Treatment.—An adequate fluid intake was maintained by the oral route supplemented by intravenous injections. Vitamin B complex and ascorbic acid were given intramuscularly. Four grams of sodium chloride were included in the daily diet. Plasma and blood were given on several occasions. Para-aminobenzoic acid (PABA), 2.5 Gm. in 25 cc. of a 5 per cent solution of sodium bicarbonate was given by mouth every two hours for the first two days. The blood concentration of para-aminobenzoic acid was only 4 mg. per hundred cubic centimeters at the end of this time. Accordingly, the dosage was increased to 5 Gm. every two hours in 50 cc. of a solution of sodium bicarbonate. In twenty-four hours the blood level was 18 mg., and a day later 32 mg., per hundred cubic centimeters. The temperature dropped sharply on the fifth day, reached normal on the sixth day and remained there. The rash faded with great rapidity on the sixth day, the sensorium cleared overnight and the boy was practically well. The Weil-Felix agglutination test with Proteus OX 19 was positive in a dilution of 1:2,560 on June 16, and the complement fixation reaction was positive for Rocky Mountain spotted fever in a dilution of 1:256 on June 12.

In comparison with experience with Rocky Mountain spotted fever in the past, this was a brilliant therapeutic result in a rather severe case. Ordinarily this boy might have been expected to be extremely sick for two to three weeks. The course of extremely severe and moderately severe cases treated prior to para-aminobenzoic acid therapy are shown in charts 2 and 4.

CASE 2.—*History.*—P. M.,[15] a white girl aged 4, was admitted to the Sternberger Children's Hospital July 24, 1946 with a history of tick bite, high fever and chills for seven days and rash and delirium for four days.

Physical Examination.—The child appeared to be extremely ill; she was delirious, dehydrated and incoordinate; she breathed rapidly and deeply. The pulse rate was 148 and blood pressure 82 systolic and 60 diastolic. There was a generalized hemorrhagic macular rash, which was most intense on the face, buttocks and extremities, and a palatal enanthem. The spinal fluid was normal chemically and cytologically. The carbon dioxide combining power of the blood was 32 volumes per cent, the serum protein level was 5.9 Gm. per hundred cubic centimeters and the Widal reaction and agglutination against Proteus OX 19 were negative.

Treatment.—Dehydration and acidosis were rapidly overcome with the administration of sixth-molar sodium lactate and dextrose in lactate-Ringer's (Hartman's) solution parenterally. She was given 3 Gm. of para-aminobenzoic acid every two hours by mouth (1 Gm. per pound [0.5 Kg.] of body weight per twenty-four hours) and adrenal cortical extract, vitamin B complex, ascorbic acid and vitamin K parenterally. Plasma and blood were administered at appropriate intervals. Defervescence began the third day and was complete on the fourth. The rash faded with great rapidity after the fourth day, in striking contrast to its usual course in severe Rocky Mountain spotted fever. Ordinarily in this condition the rash becomes progressively more intense, widespread and hemorrhagic for at least two weeks.

This also may be described as a brilliant therapeutic triumph in an exceedingly ill child whose febrile fastigium in the pre-para-aminobenzoic acid era would probably have exceeded two weeks in duration. It is worthy of note that this patient was already in acidosis on admission and that without adequate laboratory control this factor alone might have become extremely serious. The blood level of para-aminobenzoic acid was 66 mg. on the third day and 54 mg. per hundred cubic centimeter on the fourth day after the dose had been decreased to 2 Gm. every two hours.

CASE 3.—*History.*—F. W., a white girl aged 10, entered the Sternberger Children's Hospital Aug. 10, 1946 with a history of tick bite two weeks before, headache, chills, high fever and backache for seven days and rash and inconstant delirium for five days before admission.

Physical Examination.—Positive observations on physical examination were: dehydration; the typical hemorrhagic rash of Rocky Mountain spotted fever, involving the entire body but with maximum intensity on the extremities; conjunctivitis; strawberry tongue; moderate edema; positive Brudzinski and Kernig's signs, and a rapid pulse. The spinal fluid yielded normal cytologic and chemical findings, and urinalysis and the blood count were also negative, as was agglutination against Proteus OX 19. The serum protein level was 5.76 Gm. per hundred cubic centimeters.

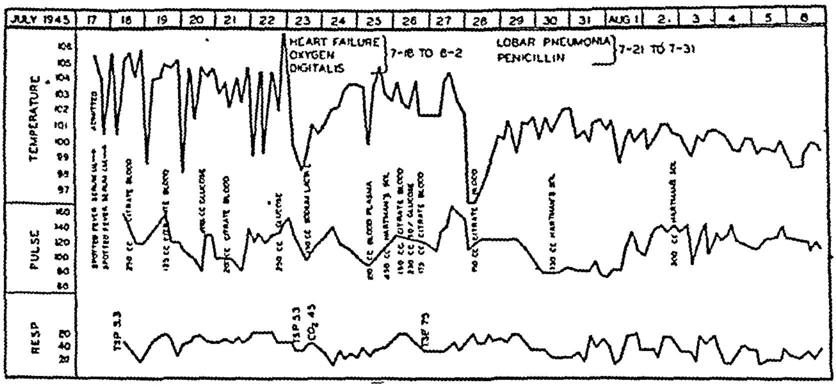

Chart 4 (R. L. P.).—Extremely severe case of Rocky Mountain spotted fever in 1 year old boy, treatment prior to para-aminobenzoic acid.

Treatment.—Intravenous dextrose in lactate-Ringer's solution and plasma were given in adequate amounts, and a high intake of vitamins A and B complex, ascorbic acid and vitamins D and K was maintained. Six grams of para-aminobenzoic acid was given on admission, and then 3 Gm. was given every two hours, with 10 cc. of a chilled solution of 5 per cent sodium bicarbonate per gram. The carbon dioxide combining power of the blood was 32 volumes per cent on the second day and 52 on the third. The temperature dropped to normal and the rash began to fade rapidly on the third day. The patient was practically well at the end of a week. There was a weight loss of 6 pounds (2.7 Kg.) in six days—obviously from loss of edema fluid. Blood obtained on the ninth day agglutinated Proteus OX 19 in a dilution of 1:320 and gave a positive complement fixation for Rocky Mountain spotted fever in a dilution of 1:512.

This appeared to be an excellent result in a moderately severe case of the disease.

CASE 4.—*History.*—L. S., a white girl aged 3, was admitted to the Sternberger Children's Hospital Aug. 9, 1946, complaining of fever and chills for four days, rash for three days and vomiting for one day.

Physical Examination.—The child looked sick but was conscious and not dehydrated. There was a generalized pink macular and papular rash, most intense on the extremities and buttocks and present on the palms and soles. The remainder of the examination revealed essentially normal conditions.

---

[15] This case is reported through the courtesy of Dr. Roy M. Smith, Greensboro, N. C.

Treatment.—The child was given an adequate amount of fluids and vitamins and 3 Gm. of para-aminobenzoic acid every two hours. The temperature dropped to normal in twenty-four hours, and the rash faded. The administration of para-aminobenzoic acid was discontinued on the fifth day. On that day her blood serum agglutinated Proteus OX 19 in a dilution of 1:640 and the complement fixation test for Rocky Mountain spotted fever was positive in a dilution of 1:32.

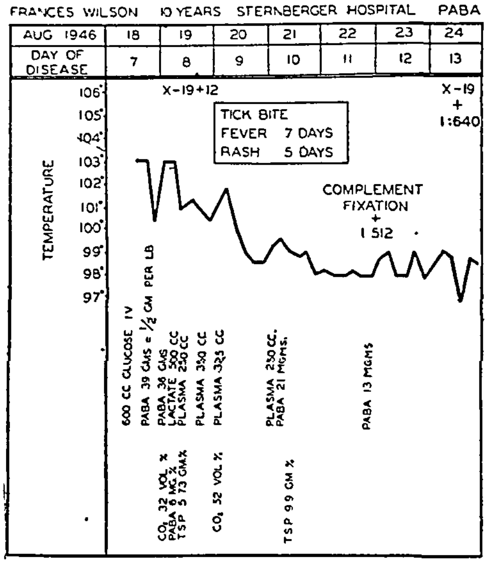

Chart 5 (case 3).—Excellent result with para-aminobenzoic acid therapy.

This was a mild case of the disease which, however, under treatment with para-aminobenzoic acid terminated with astonishing speed. By way of contrast the chart is shown (chart 7) of a boy (before para-aminobenzoic acid) with spotted fever so mild that he had no trace of rash. Defervescence was not complete until the fourteenth day of the disease.

Case 5.—*History.*—F. W., a white girl aged 5, entered the Sternberger Children's Hospital June 26, 1946 with a history of tick bite, fever and chills for six days, rash for four days and vomiting and delirium for two days.

Physical Examination.—The child appeared to be decidedly ill, was dehydrated and delirious. There was a fine hemorrhagic rash all over the body, most intense on the face and extremities and present on the palms and soles. Conjunctivitis, a coated tongue and a pulse rate of 160 were noted. The heart and liver were not enlarged.

Treatment.—A solution of dextrose in lactate-Ringer's solution and amigen was given intravenously; vitamins A and B complex, ascorbic acid and vitamins D and K were furnished in large amounts, and para-aminobenzoic acid, 2 grams per pound (0.5 Kg.) (5 Gm. every two hours in 40 cc. of a 5 per cent solution of sodium bicarbonate), was prescribed. After twelve hours there was considerable abdominal distention, which was attributed to the sodium bicarbonate. Accordingly, for the next twelve hours the dosage of this was reduced to 40 cc. of 2.5 per cent solution for each 5 Gm. of para-aminobenzoic acid. The next morning the clinical impression of acidosis was proved correct by a blood carbon dioxide combining power of 31 volumes per cent. The level of para-aminobenzoic acid in the blood was 65 mg. per hundred cubic centimeters. Acidosis was corrected with sodium lactate solution and the dosage of para-aminobenzoic acid reduced to 2 Gm. every two hours. The next morning the blood level was 120 mg. per hundred cubic centimeters, and administration of the drug was stopped. That evening the child went into a virtual collapse. The serum protein level, which had been 6.4 Gm. on admission, was found to be only 3 Gm. per hundred cubic centimeters. She was given 25 Gm. of serum albumin (obtained by courtesy of Dr. George Harrell) intravenously and later given plasma in large amounts. On the fifth day the para-aminobenzoic acid blood level was 80 mg., the serum protein level 5.38 Gm. per hundred cubic centimeters, and the temperature normal, but the child looked sick and was delirious. That evening fever and signs of cardiac failure developed, and by the next morning lobar solidification was present in the right lung. The para-aminobenzoic acid blood level was found to be zero. Para-aminobenzoic acid, 0.75 Gm. per pound (0.5 Kg.) of body weight, digitalis and penicillin were given. After four days of high fever the para-aminobenzoic acid level was 30 mg. per hundred cubic centimeters, and the dose was increased to 1 Gm. per pound (0.5 Kg.). The temperature dropped to normal in three days, and the child went on to an uneventful recovery. Blood obtained July 10 agglutinated Proteus OX 19 in a dilution of 1:320 and showed complement fixation which was positive in a 1:4 dilution for Rocky Mountain spotted fever.

This case was improperly handled in several respects: (1) too much para-aminobenzoic acid was given, and intoxication resulted; (2) too little sodium bicarbonate was used to buffer the para-aminobenzoic acid, with the result that acidosis was produced, and (3) the administration of para-aminobenzoic acid was stopped too soon, the level of the drug in the blood fell to zero overnight and a relapse with heart failure and pneumonia developed. When proper amounts of the drug were then given, rapid recovery ensued. Reliance was placed on the intravenous injections of amino acids to maintain adequate protein levels, although Harrell, Venning and Wolff[3] pointed out that this measure alone may not raise the blood protein concentration, since the ability of the liver to synthesize protein is often impaired in this disease. In spite of the administration of apparently adequate amounts of amino acids the serum protein level fell to 3 Gm. per pound (0.5 Kg.), circulatory failure supervened and only prompt administration of serum albumin and plasma averted a catastrophe.

COMMENT

In none of these patients was any difficulty encountered in the administration of the para-aminobenzoic acid, but gavage may be necessary in unconscious patients. The drug was given in a cold 5 per cent solution of sodium bicarbonate. Acidosis developed in 1 patient whose dose of para-aminobenzoic acid was too great (3 Gm. per pound [0.5 Kg.] of body weight) and was not adequately buffered with sodium bicarbonate solution. White blood cell counts were made at frequent intervals on every patient, but in no instance did leukopenia develop. The impression was

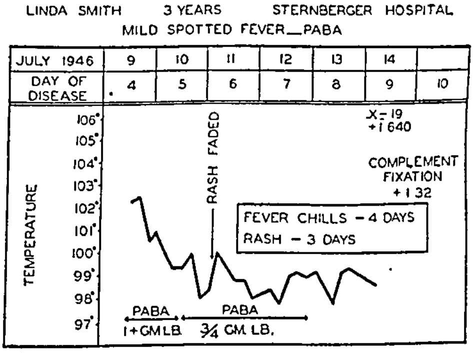

Chart 6 (case 4)—Mild case of Rocky Mountain spotted fever with para-aminobenzoic acid therapy.

obtained that abdominal distention and some degree of delirium were possibly due to the para-aminobenzoic acid. Several patients continued to be irrational after becoming afebrile, and in each instance the sensorium cleared as soon as the administration of para-aminobenzoic acid was stopped.

The striking thing about these patients was the amazing speed with which the temperature dropped, the rash faded and recovery ensued, as soon as adequate concentrations of para-aminobenzoic acid in the blood were achieved.

TREATMENT PLAN

The following comprehensive plan, summarized in the accompanying table, is proposed for the treatment of Rocky Mountain spotted fever:

1. The fluid and electrolyte balance should be restored to normal by means of intravenous injections of dextrose in saline or lactate-Ringer's solution. It should then be maintained at the normal level by the oral intake of fluids and added sodium chloride. It has been pointed out by Harrell, Venning and Wolff[3] that intravenous injections of electrolytes in solution in a patient whose serum protein is too low will serve only to produce more edema and, possibly, circulatory failure with pulmonary edema.

Comprehensive Plan for the Treatment of Rocky Mountain Spotted Fever

1.—Restore and maintain fluid and electrolyte balance with dextrose and saline or lactate-Ringer's solution.
2.—Correct acidosis with one-sixth molar sodium lactate.
3.—Maintain protein level with high protein diet, plasma, serum albumin and blood.
4.—Furnish vitamin needs with vitamins A, C, D, K and B complex (liver failure).
5.—Give para-aminobenzoic acid (PABA), 0.5 to 1 Gm. per pound (0.5 Kg.) of body weight per day, depending on the patient's size; at two hour intervals; buffer it with 10 cc. of chilled 5 per cent solution of sodium bicarbonate per gram; determine the blood level of the drug daily if possible; levels of 30 to 60 mg. per hundred cubic centimeters desirable; 60 to 80 mg. may be necessary; above 80 mg. are hazardous.
6.—Watch for possible toxic effects of para-aminobenzoic acid: acidosis, leukopenia, abdominal distention and delirium.
7.—Be on the alert for complications: heart failure (digitalis), pneumonia (penicillin usually no good) or encephalitis.
8.—Adequate laboratory studies are virtually a necessity.
9.—A soluble salt of para-aminobenzoic acid for parenteral injection is desirable.

2. Acidosis should be corrected by intravenous and subcutaneous injections of sixth-molar sodium lactate solution in appropriate dosage.

3. The serum protein level of the blood, depleted in this disease by starvation, vascular damage and hepatic failure, should be restored to normal by intravenous injections of plasma (and, in emergencies, of serum albumin). This level should be maintained by further injections of plasma at appropriate intervals and by a high protein diet (fed by gavage if necessary). If anemia develops, transfusion of blood should be given freely.

4. A high intake of vitamins should be furnished by mouth, by gavage or by the parenteral route if necessary. Thiamine is given to help prevent shock, ascorbic acid to obviate endothelial damage to blood vessels, vitamins B complex and K for damage to the liver and for increased prothrombin time.

5. Para-aminobenzoic acid, 0.5 to 1 Gm. per pound (0.5 Kg.) of body weight per day, is given, depending on the size of the patient. Small children get 1 Gm. per pound (0.5 Kg.); large children get half this much; the children of intermediate size get about 0.75 Gm. This is partially buffered with 10 cc. of a 5 per cent solutiion of sodium bicarbonate per gram in order to prevent acidosis and nausea and is given at two hour intervals. The drug is excreted with such rapidity that its administration at two hour intervals is essential in order to maintain an adequate concentration of it in the blood and tissues. The blood level should be estimated[13] each day at approximately the same time with reference to a dose of the drug. A level of 30 to 60 mg. per hundred cubic centimeters is desirable; a level of 60 to 80 mg. may be necessary to obtain the best results; concentrations above 80 mg. may be hazardous. Administration of the drug is usually continued for several days after the temperature has returned to normal.

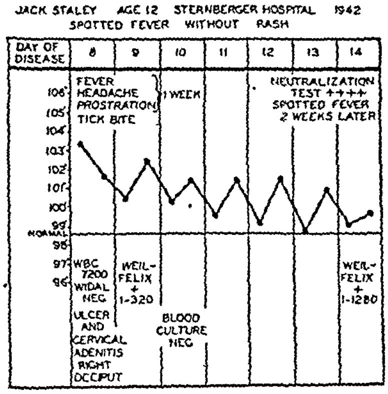

Chart 7 (J. S.)—Mild case of Rocky Mountain spotted fever without rash in boy aged 12; treatment prior to para-aminobenzoic acid.

6. The possible toxic effects of para-aminobenzoic acid should be watched for: acidosis, leukopenia, abdominal distention and delirium. If the white blood cell count falls below 3,000 the administration of para-aminobenzoic acid should be discontinued. Tympanites and delirium occur fairly frequently but are probably of little importance.

7. The complications of Rocky Mountain spotted fever should be carefully looked for: congestive cardiac failure (for which oxygen and digitalis in full doses are helpful); pneumonia (usually lobar, probably rickettsial, often not helped by penicillin, which should always be given); encephalitis, and thrombophlebitis. The cardiac failure is usually reversible, and when recovery occurs it is complete.

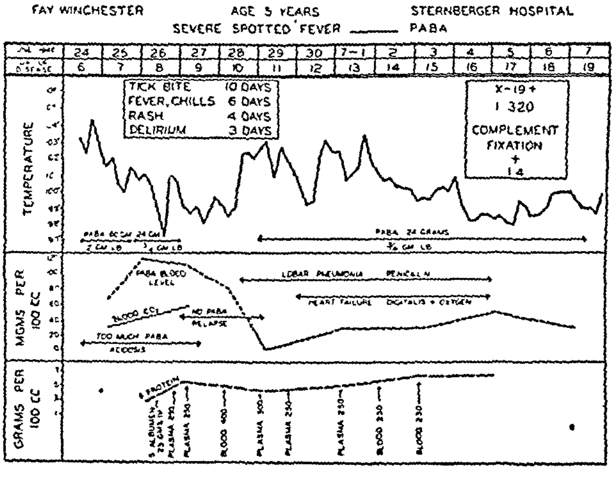

Chart 8 (case 5).—Severe case of Rocky Mountain spotted fever with para-aminobenzoic acid therapy.

8. It is possible but difficult to treat these patients without adequate laboratory control. Frequent determinations of the carbon dioxide combining power and the serum protein and para-aminobenzoic acid levels of the blood are virtually a necessity, while determinations of the nonprotein nitrogen and chloride blood levels and of the prothrombin time may be valuable aids.

9. It would be extremely helpful if a soluble preparation of para-aminobenzoic acid were available for parenteral injection in order to rapidly initiate treatment in the unconscious or vomiting patient.

10. It must be emphasized that para-aminobenzoic acid alone is not the sole answer to this therapeutic problem but constitutes an extremely important specific adjuvant comparable to insulin in diabetic coma or sulfadiazine in meningococcic septicemia and bacillary dysentery.

CONCLUSIONS

1. Rocky Mountain spotted fever is a common, serious and often fatal disease in this country.

2. Intelligently chosen and properly controlled supportive therapy is extremely helpful.

3. When para-aminobenzoic acid in adequate dosage is combined with proper supportive therapy, a rapid and brilliant therapeutic triumph is achieved.

4. The results obtained in 5 patients with Rocky Mountain spotted fever treated with this drug suggest that deaths from this fearful disease may be practically eliminated by such combined therapy.

INTESTINAL TUMORS OF DYSENTERIC ORIGIN

DANIEL N. SILVERMAN, M.D.
and
ALAN LESLIE, M.D.
New Orleans

In any general discussion of intestinal tumors it is proper that principal attention be paid to the malignant neoplasms, which constitute the majority of such tumors. Almost all of these are confined to the colon, arising from tissue of ectodermal origin. It is common knowledge that such malignant tumors may arise in the small intestine as well, although these are rare. Benign tumors of ectodermal origin, such as polyps, are again common in the colon and rare in the small intestine. Malignant neoplasms of mesodermal origin are far fewer than carcinomas and are about equally frequent in small and large intestine. Benign mesodermal tumors are rare and seem to have a predilection for the upper and lower ends of the small intestine.

Although inflammatory intestinal tumors have not been recognized with any frequency until recent years, Virchow [1] as early as 1853 described inflammatory tumors or "pseudotumors" of the bowel, and Moynihan [2] and Mayo-Robson [3] published case reports of such lesions in 1907 and 1908, respectively. If intraperitoneal collections of pus undergoing organization are excluded, these tumors are almost invariably of a granulomatous nature. Tuberculosis is perhaps most commonly responsible for tumors of this type and can cause their formation anywhere in the small or large intestine, the ileocecal region being their site of predilection. Other infectious granulomas of more or less classic nature related to the intestinal tract have been extensively described as occurring in the course of lymphogranuloma inguinale, actinomycosis, blastomycosis, syphilis and anthrax.[4] Occasionally there is evoked a granulomatous response to the presence of a foreign body lodged in or apposite to the intestinal wall. Impairment of local intestinal vascularity following the repair of strangulated hernias has been described as underlying an inflammatory response characterized by the formation of a granuloma. In all these instances a specific nature of the granuloma is demonstrable. Granulomas have been described as occurring after simple, penetrating, isolated or solitary ulcers of the colon or terminal ileum. From the nature of the pathologic process it is reasonable to surmise that a specific cause existed but was not demonstrated in many of these instances. "Hyperplastic appendicitis" and "typhlitis" have even been presented as causes of ileocecal granulomas.[4a]

An interesting group of nonspecific granulomas has come to light with the advancing knowledge of nonspecific inflammatory intestinal diseases. The formation of polyps of the colon is a common outcome of the competition between destruction and repair in the course of nonspecific ulcerative colitis. A slight variation in the homeostatic response may result in the formation of typical inflammatory granulomas, which can appear anywhere in the colon. Ileocecal tumor is an occasional accompaniment of regional enteritis,[5] a disease in which there is also a parallelism of destruction and regeneration. When the pathologic process extends across the ileocecal sphincter, as it does when the disease takes the form of an ileocolitis, the picture is indistinguishable from that which occurred in a case of bacillary infection to be reported later in this paper.

In the present paper we are reporting 6 cases of inflammatory intestinal tumors of specific nature occurring as a complication of amebic or bacillary involvement of the intestine. The occurrence of such tumors in the course of amebiasis are receiving an increased amount of attention because of the heightening consciousness of the high prevalence of amebiasis in this country and because of the therapeutic implications which depend on the differentiation of these from malignant colonic neoplasms. Amebic granulomas, occurring as they do only in the colon, cannot be distinguished radiologically from cancer. In fact, in most of the cases hitherto described and 2 of those to be here reported the patients were subjected to unnecessary laparotomy because of the preoperative diagnosis of colonic neoplasm. Intestinal obstruction with or without a preceding history of diarrhea, inanition, perhaps a palpable abdominal mass and roentgenographic demonstration of an obstructing lesion of the colon constitute diagnostic pitfalls which can deceive all but the most wary. Since there is such variation in therapy and prognosis, it is doubly important to distinguish these amebic granulomas from malignant tumors.

From the Southern Baptist Hospital and Lakeshore Hospital.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

[5] Cave, H. W.: Inflammatory Lesions of Small Intestine: Surgical Aspects, J. A. M. A. **127:** 456-458 (Feb. 24) 1945. Crohn, B. B.; Ginzburg, L., and Oppenheimer, G. D.: Regional Ileitis; Pathologic and Clinical Entity, ibid. **99:** 1323-1329 (Oct. 15) 1932.

We wish to call special attention to 1 case of ileocecal inflammatory tumor occurring in bacillary dysentery and 1 such tumor in combined amebic and bacillary disease. Although the occurrence of inflammatory tumors in the course of chronic bacterial dysentery is admittedly rare, bizarre manifestations of this protean disease are to be anticipated, and such cases may be expected to occur with greater frequency in the future. This statement is made in view of the present widespread dissemination of infection due to Bacterium dysenteriae throughout the United States, as foreseen by Silverman[6] in his early report of cases from the South in 1926.

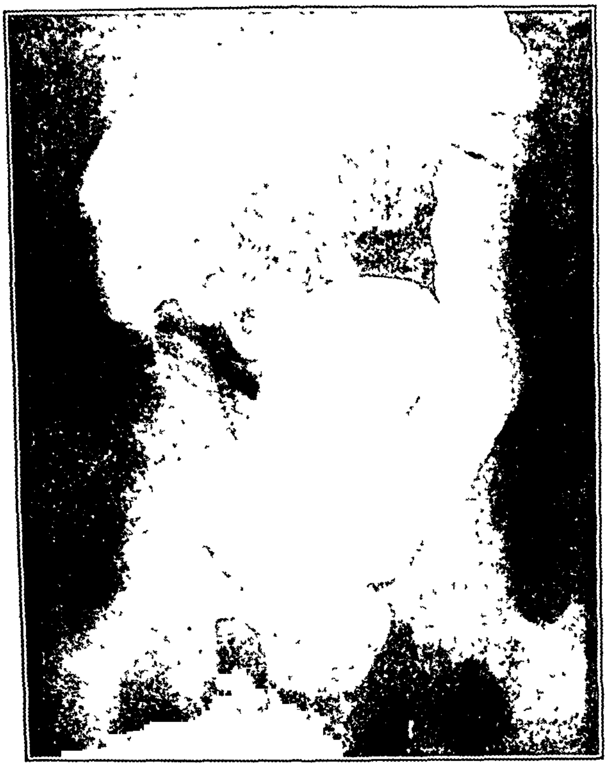

Fig 1 (case 1).—Barium enema showing ileocecal tumor.

REPORT OF CASES

Case 1.—A. R., a white man aged 19, was seen in 1942 with a one year history of cramplike lower abdominal pain, constipation and intermittent chills and fever. An appendectomy had been performed when the patient was 6 years of age. His mother had died of Hodgkin's disease.

Physical examination revealed essentially normal conditions. Proctosigmoidoscopy disclosed a reddened mucosa and spastic musculature but no ulceration or bleeding points. Barium enema showed a large filling defect involving the cecum and the ascending colon (fig. 1). Serial interval roentgenologic studies of the small intestine showed a constant irregular narrowing of the terminal 5 cm. of the ileum, with possible fistulous tracts between this segment of the ileum and the cecum. Culture of the stool resulted in the isolation of an organism of the Bacterium flexneri group

A course of vaccine therapy was instituted and, along with dietary and supportive management, was continued for three months, at which time the barium enema examination was repeated. Except for an increase in the stricture at the ileocecal level the observations were similar to those previously described. Because of this failure to improve with medical management a one stage resection of the tumor was performed, with anastomosis of the ileum to the transverse colon Microscopic examination of the tumor showed granulomatous inflammation. After the operation the patient made an uneventful recovery, and he has been asymptomatic ever since.

Case 2—M. H., a white man aged 51 with a past history of acute nephritis following yellow fever at age 18 and typhoid fever at age 21, which was complicated by cholecystitis, leading to a cholecystectomy six years later A duodenal ulcer was diagnosed clinically and roentgenologically at age 41. Roentgen examinations over a sixteen year period continued to show the duodenal deformity.

The present illness was of short duration and marked only by intermittent rectal bleeding Rectal examination revealed infiltration of the rectal wall, and proctoscopy showed, in addition to numerous ulcers in the rectum and sigmoid, an ulcerated tumor mass about 1 inch (2 5 cm) in diameter, 3 inches (7.6 cm.) above the anus. Vegetative forms of Endameba histolytica were seen on direct smears.

Therapy with emetine hydrochloride and Diodoquin resulted in the disappearance of symptoms and the complete regression of all lesions

Since his recovery from the amebic infestation the patient has been treated medically for intermittent symptoms attributable to his chronic duodenal ulcer.

Case 3.—A. B. was a white man aged 25, recently discharged from the Army, with a two and one-half year history of intermittent abdominal pain, which radiated from the epigastrium to the suprapubic region, and which was aggravated by most foods but not by milk, and was relieved by alkali. Examinations after a barium meal and enema which were performed while the patient was in the Army were said to have been negative. An appendectomy was performed but did not bring any relief. Intermittent diarrhea was noted for the last two years, and streaks of blood were seen in the stool six months before the patient's admission to the hospital.

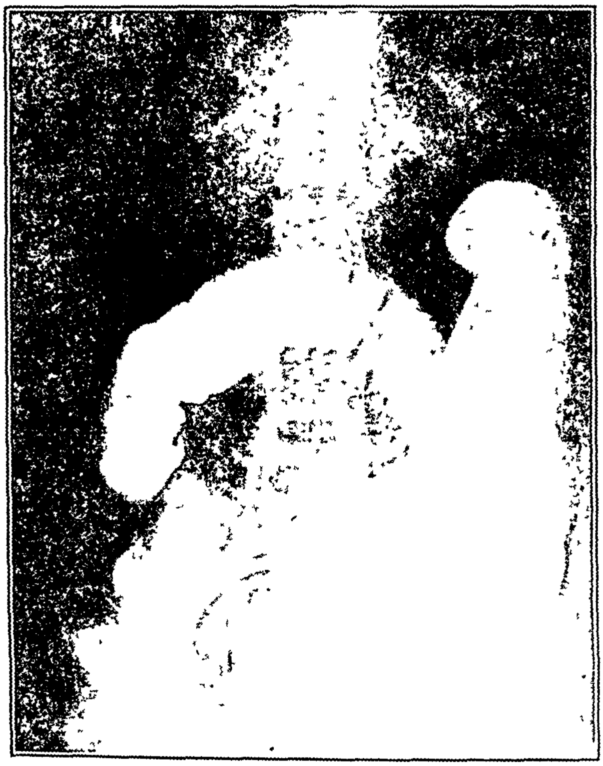

Fig 2 (case 3).—Barium enema showing large ileocecal filling defect

Physical examination revealed essentially normal conditions except for the presence of a hard, slightly tender, irregular mass in the right lower quadrant, in the line of the cecum, about 4 cm. in width and 10 cm. in length. Rectal examination revealed normal conditions. Proctosigmoidoscopy repeated several times did not show any mucosal abnormality. Examination of the saline-purged stool failed to show the presence of E. histolytica. Culture of this stool resulted in the isolation of Bacterium shigae. Examination of the colon by means of a barium enema revealed a "large, irregularly annular, filling defect of the cecum and proximal ascending colon, sharply demarcated from the apparently normal distal gut" (fig. 2). The terminal few centimeters of the ileum were apparently involved by the same process.

[6] Silverman, D. N Chronic Bacillary Dysentery, M. Clin. North America 9: 1167 1171 (Jan) 1926. The Increasing Incidence of Bacillary Dysentery, editorial, J. A M. A **121:** 1158 (April 3) 1943.

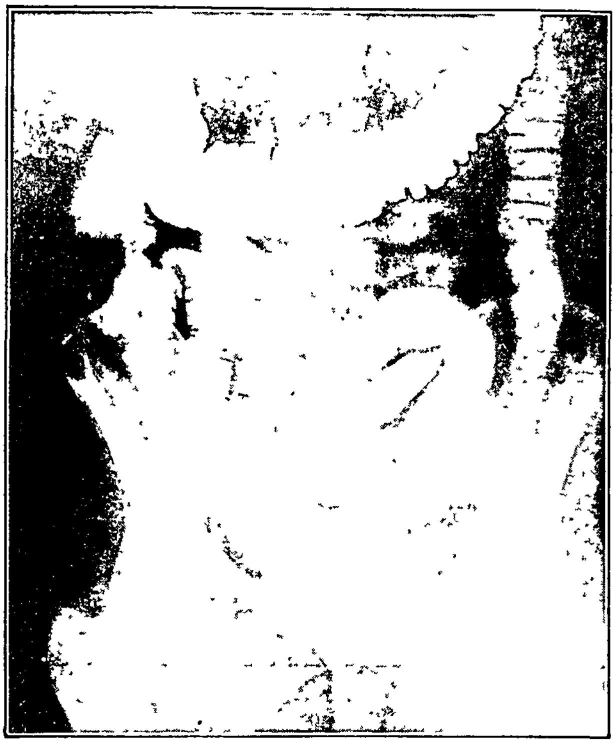

Fig. 3 (case 5).—Barium enema showing tumor of cecum.

With resection of the tumor in view, an ileotransverse colostomy was performed. At laparotomy the cecum presented itself as a hard, movable mass, and the postoperative surgical diagnosis was carcinoma. Section of an iliac node biopsy showed inflammation. The terminal ileum appeared to be inflamed and was continuous with the mass. The patient ran a stormy postoperative course marked by intestinal obstruction, for which an ileostomy was done, sepsis and death on the forty-first postoperative day.

Autopsy revealed the mass as described, a section of which showed trophozoites of E. histolytica and multiple amebic abscesses of the liver. Culture of material from the tumor and from the abscesses failed to demonstrate B. shigae.

Case 4.—Dr. A. E. was a white man aged 68, with a four day history of frequent mucosanguineous stools, following two years of intermittent diarrhea and loss of weight of 15 pounds (6.8 Kg.). Physical examination revealed essentially normal conditions except for the rectal examination, which disclosed the presence of a hard mass on the left lateral wall about 3½ inches (9 cm.) from the anal margin and extending toward the posterior wall. The proctoscopic appearance was that of an ulcerating neoplasm. Smears from these ulcers, however, showed numerous motile trophozoites of E. histolytica. In order to rule out concomitant carcinoma a biopsy was made from the margin of the tumor, the section being reported as "tumefied nodule . . . with . . . E. histolytica as the causative factor. No evidence of malignancy." Culture of the bowel contents was negative.

Vigorous antiamebic therapy resulted in the complete disappearance of the tumor mass with restitutio ad integrum.

Case 5.—Mrs. A. E. was a white woman aged 63, the wife of Dr. A. E. (case 4), with a one year history of intermittent attacks of abdominal distention and cramps in the right lower quadrant accompanied with low grade fever. Physical examination revealed essentially normal conditions except for resistance to deep palpation of the right lower quadrant. Barium enema showed the presence of a large filling defect of the cecum (fig. 3).

With a preoperative and postoperative surgical diagnosis of carcinoma of the cecum, resection of the cecum with side to side anastomosis of the colon was performed. The specimen disclosed a large necrotic ulcer of the cecum, approximately 1.5 by 1.75 cm., having an indurated base with several smaller satellite ulcers. Smears taken from the ulcer showed motile trophozoites of E. histolytica; sections disclosed a chronic inflammatory granulomatous appearance with no evidence of cancer.

After this circuitous arrival at a diagnosis, antiamebic therapy was instituted and the patient recovered.

Case 6.—J. T. was a white man aged 52 with a two week history of lower abdominal pain and mucosanguineous diarrhea accompanied with low grade fever. The previous history was irrelevant.

Physical examination revealed essentially normal conditions except for tenderness throughout the lower part of the abdomen. Proctoscopic examination revealed infiltration of the bowel wall and multiple necrotic ulcers at the rectosigmoid junction. Barium enema showed a filling defect at the rectosigmoid junction (fig. 4). The clinical diagnosis was carcinoma, but smears from the ulcers showed numerous motile trophozoites of E. histolytica.

With antiamebic therapy there was complete disappearance of the lesion and regression of symptoms.

COMMENT

Recently, we[7] described 3 fatal cases of amebic colitis characterized by an extensive ulceronecrotic process. Two of these cases were complicated by concomitant infection with a dysentery organism, which may explain in part the fulminating course. In case 3 of the present paper, the response of the bowel to the presence of amebas was the formation of a large granuloma without other demonstrable pathologic condition. Although the patient died postoperatively, it is reasonable to infer that the fatal outcome was promoted by the presence of the B. shigae. In all these cases, however, the pri-

[7] Silverman, D. N., and Leslie, A.: Intractable Amebic Colitis with Special Reference to the Ulceronecrotic Form, J. A. M. A. 129: 187-190 (Sept. 15) 1945.

mary agent of death was probably the ameba. It is difficult to explain why on the one hand there is a necrotizing process and on the other a granulomatous response evoked by the same organism. For a facile explanation it might be conjectured that there is a competition between the destructive activity of the ameba and the regenerative power of the host. If the infestation is sudden and overwhelming there is no time for marshaling the defenses against the invasion, and the unopposed histolytic activity of the ameba results in the severest form of the disease. This set of circumstances was observed by Faust[8] to occur in outlanders who entered areas of amebic hyperendemicity. In such regions the natives apparently enjoy a degree of immunity, or at least resistance, to the extreme manifestations of the disease, because the incidence of infestation is high while the incidence of clinical symptoms is low. As a corollary to this observation, it may be stated that many of the reports of cases of amebic granulomas come from South America,[9] where amebic infestation is widespread. If this resistance exists or the initial infestation is not tremendous, the local regenerative process may be excessive in certain persons, ultimately resulting in the formation of a tumor. In view of the high incidence of amebic infestation this explanation is inadequate to account for the relative infrequency of amebic granulomas. Although there are various strains of E. histolytica, there are too many gaps in our present knowledge for us to do any more than mention the possibility of specific strains associated with the granulomatous response. Perhaps an undiscovered concomitant infection due to B. dysenteriae may contribute to the provocation of this response.

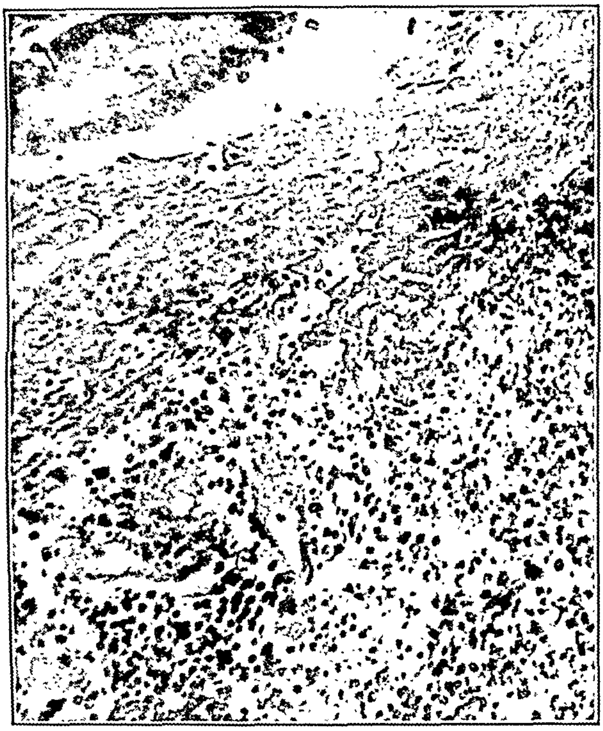

Fig. 5 (case 3).—Photomicrograph of cecal tumor.

The outstanding and almost universal characteristic of amebic granulomas is their response to specific therapy. The rapid resolution of large tumors after the administration of emetine hydrochloride can only be compared with the melting away of syphilitic gummas after exhibition of the iodides. An amebic granuloma in which extensive fibrosis has taken place may require surgical intervention, but this should not be considered until thorough amebicidal therapy has proved inadequate. Large tumors are seen to disappear after medical therapy alone, as was shown in cases 2, 4 and 6 herein reported. The large granuloma associated with the infection with B. flexneri (case 1) did not respond to autogenous vaccine therapy, and since there was no more specific type of therapy available at the time the patient was observed, a surgical resection was successfully performed. It may be that antibiotic therapy, when more highly developed, will be effective in such cases. It should be noted that inflammatory tumors occurring in the course of bacterial dysentery must be exceedingly infrequent, since search of the recent literature failed to disclose other such cases. It is probable, however, that many of the inflammatory tumors heretofore described were bacterial in etiology, the organism being elusive and not successfully cultured.

The importance of correct diagnosis is basic and elementary, but particular importance is attached to making the correct diagnosis of a disease for which specific therapy is curative. The fatality reported herein might have been avoided had amebicides been administered. If the tumor had been resected in one stage, as was done in case 5, the pathologist would have provided the diagnosis and antiamebic therapy would have been instituted. It should in most cases, however, be unnecessary to enlist the surgeon's aid to establish a diagnosis of amebiasis. Rectal scrapings or even a biopsy if a tumor is within reach of the sigmoidoscope can be diagnostic. If amebic granulomas are considered in the differential diagnosis of tumors of the colon, careful examination of the saline-purged stool will in most instances of amebic tumors reveal the protozoon.

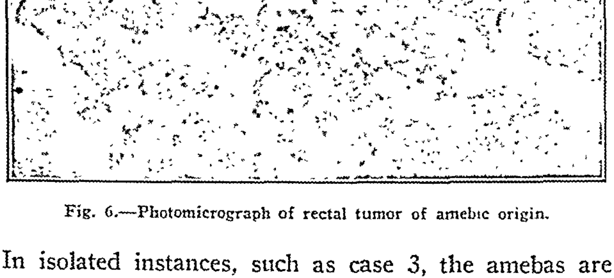

Fig. 6.—Photomicrograph of rectal tumor of amebic origin.

In isolated instances, such as case 3, the amebas are present only in the depths of the tumor mass and elude the parasitologist, to the detriment of the patient. Although it is contrary to scientific instincts to give specific treatment without a specific diagnosis, a case such as this gives one pause, and in the younger age group at least, when the history is at all suggestive, such action might well be justified.

The problem of amebic granulomas is no longer regional, limited to the South and the tropics as heretofore believed. Cases of amebic tumors are reported from northern areas. Likely and Lisa[10] reported 1 case of granuloma of the large intestine associated with amebiasis in the state of New York, and in 1935[11] an amebic tumor was presented as a Cabot case in Boston.

SUMMARY

1. Six cases of inflammatory intestinal tumors are reported. Four of these were amebic granulomas, 1 a granuloma occurring in combined amebic and bacillary disease and 1 a granuloma in uncomplicated chronic infection of the bowel with Bacterium dysenteriae.

2. The diagnostic and therapeutic implications are discussed with emphasis on distinguishing these tumors from malignant neoplasms.

ABSTRACT OF DISCUSSION

Dr. Russell S. Boles, Philadelphia: I congratulate Drs. Silverman and Leslie on their alertness in recognizing these cases. Most of us are not as aware of the possibility of these lesions as we should be and as I hope we will be hereafter. One of the most important lessons that this paper teaches is the necessity of securing a very complete history of all cases. One of the most unfortunate consequences of the accelerated course for medical students and for interns that I have seen in teaching students is their indifferent attitude toward a good history, and their too ready acceptance of a roentgenologic or laboratory diagnosis. I think it is most unfortunate, and it is going to continue to cause mistakes of the kind that Dr. Silverman has pointed out here. It would be a bit small, I guess, at this time to question the use of the word tumor in these cases. "Tumor" in my conception is a mass of unknown etiology. Now, these masses that are due to the ameba are, of course, granulomatous lesions of more specific type and not, strictly speaking, tumorous. I should like to refer briefly to 2 cases that I should perhaps question a little bit. The first case: The boy 19 years of age, with a one year history of constipation. Why attribute the lesion that was demonstrated in the cecum necessarily to the Bacterium flexneri organism that was found, in view of the steady, progressive, downward course and the necessity of ultimate resection? How could the possibility of a primary hypertrophic granulomatous type of tuberculosis of the cecum be entirely eliminated? The roentgenogram suggested that this could be a primary lesion. The ulcerative types are secondary to pulmonary lesions. I believe, in 99 to 100 per cent of cases. Case 2 is remarkably interesting and unquestionably bona fide, showing a ready response to emetine therapy and ultimate regression of the tumor and the symptoms. I was interested, however, in the extremely short history given of only two weeks, yet a tumor mass had developed without any previous suggestive symptoms of intestinal pathology. In case 3 could the amebas have been coincidental? I didn't hear or see in the paper any pathologic report of the tumor aside from the finding of amebas. One must be aware, naturally, of the possibility of carcinoma being associated with amebic infestation, and whether case 3 is primarily and solely a case of amebic granulomas is in my opinion something to be considered. The role of the Bacterium shigae here—is that to be considered necessarily specific or not? Perhaps it should be so considered if it is to be assumed that the B. flexneri organism in case 1 was specific. Could that have been carcinoma in a young man, 25 years of age? It is not rare. Case 4, again, was most interesting, a bona fide amebic, specific granuloma with a regression of symptoms. This paper emphasizes the necessity for all of us to consider amebic granulomas in questionable bowel lesions. I want to ask Dr. Silverman one question: How did you treat the cases with emetine, and how long did it take for you to notice a regression of the tumor mass in the cases in which that happened?

Dr. Hyman I. Goldstein, Camden, N. J.: "Tumor" is a swelling or morbid enlargement; it is a mass of tissue (new) which persists and which has no physiologic use—not necessarily always a *benign or malignant neoplasm!* Our friend, Dr. Boles, is in error when he criticizes Dr. Silverman for speaking of a granulomatous tumor or mass! Dr. Silverman was correct. A "tumor" is any swelling or tumefaction and the word also refers to any neoplasm.

Dr. Daniel N. Silverman, New Orleans: For years we have emphasized that diarrhea is absent or only occasional in almost 80 per cent of cases of chronic infection due to Bacterium dysenteriae and amebic infestation. The pathologic process may be localized to the right colon in these conditions and produce no objective irritative manifestations. The lesions were studied microscopically. Tuberculosis may have played a part, but the organism was not found, and the pathologic changes of tuberculosis were not in evidence. We could not say that tuberculosis existed. Now concerning treatment: The amebic granuloma responds as readily to emetine hydrochloride as does the hepatic abscess, with practically complete disappearance a week to ten days after the administration of emetine is started. I might reiterate that in the cases, our own and those of others, in which there was surgical intervention, this was because the correct diagnosis was not made. In response to the question by Dr. Boles on how long it took for regression of the tumor mass, the answer is about ten or twelve days.

CHRONIC ULCERATIVE COLITIS

Proctologic Interpretation and Treatment

MARTIN SELER KLECKNER, M.D.
Allentown, Pa.

Since proctologic practice includes the study, diagnosis and treatment of all pathologic conditions of the large bowel, it is not unusual to find segmented areas of large portions of the colon involved in advanced stages of inflammatory disease. This is primarily revealed by careful history, thorough physical examination, and sigmoidoscopic findings, aided by the double contrast air enema and the laboratory examinations of smears and cultures taken from these infected parts. Such familiar pictures, in contradistinction to the acute forms of the disease, are variously spoken of as nonspecific, chronic ulcerative, thromboulcerative or idiopathic colitis. My own belief is that a combined designation (chronic nonspecific ulcerative colitis) is the most practical term, particularly when reporting this diagnostic condition to the general practitioner.

A detailed description of the pathologic and clinical picture involving the colonic mucosa in this disease would be time consuming, but a review of the splendid efforts of some of the gastroenterologists (Bargen, Bockus, Crohn, Felsen and Paulson in particular) would prove most helpful and instructive. Briefly, the primary etiologic factor in chronic nonspecific ulcerative colitis cannot be determined, but it is known that the resultant secondary invasions into the bowel wall are due to certain causes—bacterial, toxic or both. It has been the impression that these lesions of the bowel are frequently influenced by certain factors or phenomena which may alter the progress of this disease. These conditions may be due to allergic, immunologic, nervous or nutritional faults or deficiencies.

[11] Cabot Case 21312, New England J. Med. 213: 235-238 (Aug.) 1935.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Seldom do these patients seek the advice of the gastroenterologist or proctologist until both clinical and pathologic conditions have reached the chronic stage, which will usually be several months to a year after the onset of the existing trouble. The symptomatologic history elicited in these cases revealed diarrhea, blood with mucus in the stool and tenesmus as most commonly present. Dull pain or discomfort in the lower part of the abdomen, constipation (in old chronic cases), flatus, weakness and loss of weight followed in that order. Acute exacerbations of this chronic condition are not uncommonly seen, with the symptomatology greatly aggravated. Ofttimes rest in bed and hospitalization are required to combat this sudden change in the disease process of the patient.

Table 3.—*Medical (Nonsurgical) Phase of Treatment of Chronic Nonspecific Ulcerative Colitis (Private Cases)*

1. Rest (in bed if necessary)
2. Diet (nonirritating, low residue, high caloric)
3. Therapeutic test (in absence of laboratory findings):
    a. Daily subcutaneous injection of emetine hydrochloride ¾ grain (0.045 Gm.) for one week
    b. By mouth (the following have been found efficacious):
        (1) Carbarsone in capsules, 4 grains (0.24 Gm.) twice a day (10 days)
        (2) Diodoquin, 9 grains (0.58 Gm.) three times a day for 1 month
        (3) Emetine bismuth iodide (in capsule), 3 grains (0.2 Gm.) twice a day (10 to 14 days)
        (4) Chiniofon, 0.5 to 1.0 Gm. three times a day (7 to 10 days)
    c. Retention enemas: Carbarsone, 2.0 Gm. in isotonic solution of sodium chloride, 6 ounces (180 cc.) (nightly—7)
    d. Autogenous vaccines or Bargen streptococcus vaccine
    e. Antidysenteric serum

Physical examination should always include study of the oral, nasal and aural cavities as probable sites of some hidden focus of infection. The thoracic and abdominal regions may reveal other important clues which are substantiated by roentgenologic study. I have frequently found that even patients seen in the earlier stages of the disease present a slight soreness in the right iliac fossa, more so than in the left, while the abdomen itself is usually soft, even when extensive portions of the bowel are involved. It is by sigmoidoscopic examination, however, that the true diagnosis is made. Visual confirmation of these terminal bowel lesions may vary from a smooth, moderately congested mucosa with occasional pinpoint hemorrhages (brought on frequently by the passage of the sigmoidoscope through a somewhat constricted lumen) to the freely bleeding types on whom its passage may cause considerable pain and discomfort. Because of this, much difficulty may be experienced and undue chance may be taken if continued efforts are made to pass the sigmoidoscope above the rectosigmoidal junction. Repeated sigmoidoscopic and roentgenologic examinations are necessary because the diseased bowel ofttimes shows much variation in the pathologic conditions present. Aside from the occasional regional types, it has been my experience that at one time or other the rectum or rectosigmoid is, or was, usually involved in the ulcerative process of this disease; furthermore, approximately 50 per cent of my cases in private practice showed involvement which did not extend beyond the proximal limits of the rectosigmoidal area. In all these cases the diagnosis was verified by careful roentgenologic laboratory study. The cases which revealed greater involvement seemed to be rather the result of direct extension from the rectosigmoidal area, usually with the descending colon and then the transverse portion of the large bowel involved in the severer types, and often with more or less irreparable damage. These modifications and changes are greatly influenced by the virulence of the disease itself, the length of time the patient has suffered with colitis, together with the reactions which various patients displayed not only to the treatment afforded them but also to emotional disturbances. Dietary indiscretions and, to a lesser extent, some nutritional deficiencies and the avoidance of colds also influenced these modifications and changes. It is generally believed that patients with chronic nonspecific ulcerative colitis are seldom free from symptoms. In my series of private patients I have found a goodly number who seemed to be happy and minus any appreciable gastrointestinal disturbances for weeks at a time. They continued at their regular routine, several of them operating heavy cranes even though sigmoidoscopy revealed "lesions in abeyance." This I found was possible chiefly because they followed a strict regimen of living (with the usual high caloric low residue diet), and practiced the occasional self administration of certain medicaments, lately and most effectively, phthalylsulfathiazole (Sulfathalidine). I should like to mention that in the comparison between patients from private and free clinic practice, one is permitted a higher score for betterment and for cure in the former group; and, because of this and their ability "to get along pretty well," permission is less freely granted by private patients for the performance of operative procedures other than those of minor degree.

The study of the statistics given in table 1 reveals that a total number of 223 private cases of chronic colitis are reported in the period from 1940 to 1945, of which 129 (58 per cent) were ruled out as not being strictly chronic nonspecific ulcerative colitis. These patients showed considerable response to antiamebic, antidysenteric and similar types of treatment. Although many of them showed "return flare-ups" at intervals of three or four months, they never seemed to get out of "treatment control"; the patients felt well and frequently attributed these so-called relapses to their own mode of living. These 129 cases were classified by me as "near chronic nonspecific ulcerative types." Of the remainder 94, or 42 per cent, were truly cases of chronic nonspecific ulcerative colitis with an equal distribution in sex and with the disease appearing most commonly between the ages of 20 and 40. In a comparison of these with the "near" cases, in which the age limit extended from 30 to 60, I found that in this "near" group cancer was more frequently detected (9 per cent to 4 per cent).

TABLE 4.—*Chronic Nonspecific Ulcerative Colitis: Other Drug Therapy*

a. Occasional purge, prescribing castor oil, 15 to 30 cc in orange juice and sodium bicarbonate
b. Fuller's earth products alone or combined with bismuth plus camphorated tincture of opium
c. Atropine alone or combined with codeine
d. Calcium compounds (calcinum gluconate 20 to 40 grains, or 1.4 to 2 6 Gm, daily)
e. In cases in which constipation is a factor, iron with liver extracts and vitamins (see below)
f. Vitamin replacement (B complex, ascorbic acid and vitamin K, especially); (Synkayvite* 5 mg. by mouth four times a day as "K," when there is much bleeding; or Hykinone, 4.8 mg. [1 cc. hypodermically] as required)
g. The administration of amino acids by mouth or intravenously. (Parenamine, acid hydrolysate of casein fortified with dl-tryptophane, 15 per cent sterile solution in 100 cc) to provide calories and protein need, 4 calories per gram Best given with 5 per cent dextrose in isotonic solution of sodium chloride. (I have been using a new, unofficial product called "Delcos Granules," which contains amino acids, 3 2 calories per gram, by mouth)
h. Local application of 5 per cent silver nitrate solution to ulcerations through the sigmoidoscope
i. Instillations per rectum of a 5 to 10 per cent solution of bismuth subgallate in olive oil (1 to 4 ounces, 30 to 120 cc.) one or two times a day for retention, after cleansing enema
j. Insufflations via sigmoidoscope of sulfathiazole and bismuth subgallate powder every three to four days
k. Phthalyl sulfathiazole (sulfathaladine) 2 0 to 4 0 Gm. daily by mouth (it is nontoxic and requires no bicarbonate of soda: with 50 per cent recovery in stool, action is confined locally to ulcerations)

* Synkayvite is tetrasodium 2 methyl 1, 4 naphthohydroquinone diphosphoric ester; Hykinone is menadione sodium bisulfite.

TABLE 5.—*Chronic Nonspecific Ulcerative Colitis: Surgical Phase*

Preliminary (permanent single barrel) ileostomy, to be followed in two to three months by two stage colectomy (complete). Coupled with the preoperative care, there must be included the free use of whole blood, plasma and dextrose, intravenously

The earlier the cases in the absolute group were diagnosed and the shorter the duration of the disease, the better were the chances in general for apparent cure and improvement, as is observed by reference to table 2, in which 72 per cent (68 of 94) showed satisfactory results to medical or (minor) surgical treatment other than ileostomy, colectomy or both. Each of the 223 patients was given the same routine proctologic examination, and the usual roentgenologic and pathologic procedures were followed. Unless early stool examinations were done by a competent technician, the results were discounted and the studies were repeated. Cultures, smears and swabs from the involved membranes were carefully investigated and studied. Routine studies of the blood and urine included tests for syphilis, and in returned war veterans the presence of malaria was always suspected. More advanced cases demanded tests for sedimentation, blood urea, serum protein and plasma chlorides. Craig's complement fixation tests, as recommended by Kiefer, proved helpful in some of these cases in which we attempted to exclude the diagnosis of amebic disease. At times studies of hepatic function proved decidedly valuable.

Repeated study after a barium enema yielded comparative information on the extent and progress of the colonic disease. I have been particularly partial to gaining information via the double contrast barium air enemas, although use of this procedure has not met with ready response on the part of the roentgenologists, mainly because of the time required for its satisfactory accomplishment. Certainly these patients, stricken with such seriously inflamed lesions of the bowel, cannot be hurried and will frequently consume much valuable time in a busy roentgen laboratory, but unless care and patience are used I have found that the results are unsatisfactory. The frequent study of all specimens, best obtained directly from the surface of the diseased bowel itself through a sterilized sigmoidoscope, has proved the best way to determine bacterial flora. Material obtained in this manner should be examined at once and also planted on the appropriate culture medium as directed by the pathologist. Biopsy specimens, scrapings and smears were usually the materials forwarded for laboratory investigation. Frequent examinations of the feces of these patients were performed. The principal infective agents looked for were the Entameba histolytica with its cysts, the organisms causing dysentery, acid-fast bacilli (Mycobacterium tuberculosis) and the commoner parasites. The work entailed in the study of such materials by the personnel of the pathologic laboratory is well known, and their full cooperation and correct diagnosis may often spell cure to many of these patients.

The best results were always obtained when the combined efforts of the gastroenterologist, pathologist, radiologist and proctologist (or such surgeon well versed in colon operative technic) were utilized. As a proctologist, most of my work comprises surgery of the large bowel, but the medical phase in all these cases is a primary and extremely important factor. The nonsurgical measures which I employed may be noted by referring to tables 3 and 4. Unless full cooperation was procured and fairly good response to treatment was noted (in these 94 private cases) operative measures advising preliminary ileostomy were urged with colectomy to be performed later (table 5). As private patients are invariably assured of their own financial support, operative intervention was usually refused—particularly when the patient was informed that an ileostomy bag would have to be worn. There was difficulty in convincing patients in years past that a permanent colostomy for cancer of the colon, if well managed, did not require the wearing of a bag; this has proved a convincing argument to such patients. Today, difficulty is being experienced because the wearing of an appliance has been the real objection to accepting surgical intervention, even though cure from the malady is assured. The fairly long period of hospitalization with its usual three stage operative procedure before cure can be obtained has not been the reason for absolute refusal, as many may have believed. I am convinced of greater success with the continuance of efforts toward the eradication of the diseased colon (in toto) and the performance of surgical operation at those opportune times when the ulcerative processes have become fairly quiescent. After medical treatment has been given every opportunity for betterment, and radiologic interpretation of diseased colon involvement is complete (which may even be present in patients followed for one year), then preliminary ileostomy must be performed, with colectomy (in two stages) usually following within the next two or three months. This measure provides cure. With time and full cooperation on the part of the patient as to diet and local care (but with the necessity of wearing a bag), health and future happiness will come to those patients whom medical treatment alone has failed to cure.

ABSTRACT OF DISCUSSION

DR. A. W. MARTIN MARINO, Brooklyn: Chronic ulcerative colitis may give rise to serious consequences. It is primarily a medical and not a surgical problem unless serious sequelae and complications arise. The ideal treatment has not been found. Fortunately, most patients respond reasonably satisfactorily to good medical management and carry on their duties, with only occasional relapses. In a special group of patients there is an aspect of this disease at which I never cease to marvel, and it is this: periodic proctoscopic examinations of this special group of patients over a period of years will show any or all stages of chronic ulcerative colitis, and yet these patients have no symptoms and state that they feel perfectly well! It is true that these patients may suffer mild relapses from time to time, but these are of short duration and frequently follow an infection of the upper part of the respiratory tract. Some patients fail to respond to carefully planned conservative measures including diet, vitamins, sulfonamide compounds, and blood transfusions. Their fever, general malaise and bowel symptoms persist, and complications such as inability to eat, increasing abdominal distention, severe hemorrhage and perforation, ensue. Ordinarily that is the type of patient on whom I would consider performing an ileostomy with eventual colectomy. I might say that when I perform an ileostomy I transect the ileum so that the ileal stream is completely diverted. My experience with colostomy performed proximal to the disease in the colon is so discouraging that I shall dismiss that subject at this time. I have had under my care this year 4 patients desperately ill with chronic ulcerative colitis. In 1 there developed definite signs of perforation and peritonitis. All 4 patients were given 30,000 units of penicillin every three hours day and night for periods of from seven to twenty-two days in preparation for their operation. However, ileostomy was not necessary in any of these patients because in a matter of days improvement took place, and all left the hospital in a condition ranging from improved to fully recovered. I recognize that the beneficial results I have observed do not necessarily mean permanent relief, but I am sufficiently encouraged by this treatment to feel that it warrants further trial. From what I have seen, I cautiously state that the administration of penicillin in high doses may be as lifesaving a procedure as ileostomy, without the disadvantages of the latter. The more ileostomies I have performed the more I have wished that there was some other method of taking care of these patients. A colostomy performed in the course of a combined abdominoperineal resection for carcinoma of the rectum is an entirely different affair than an ileostomy. I can educate patients with colostomies so that they accept their condition as a matter of course, but it seems to me that my patients with ileostomy forlornly sit on my doorstep waiting to have the continuity of their intestine resumed. These patients with ileostomy forget that the operation was performed as a lifesaving measure, and in as much as the survivors feel perfectly well, they resent the inconvenience of the more or less constant ileal drainage, regardless of what kind of a bag they may be wearing. For that reason I have sought, for some time, to find other means of taking care of these persons. In cases in which the rectum and colon are irremediably crippled there is no alternative but ileostomy. However, antibiotics may take the place of ileostomy in some patients desperately ill with chronic ulcerative colitis.

FALSE POSITIVE TESTS FOR SYPHILIS

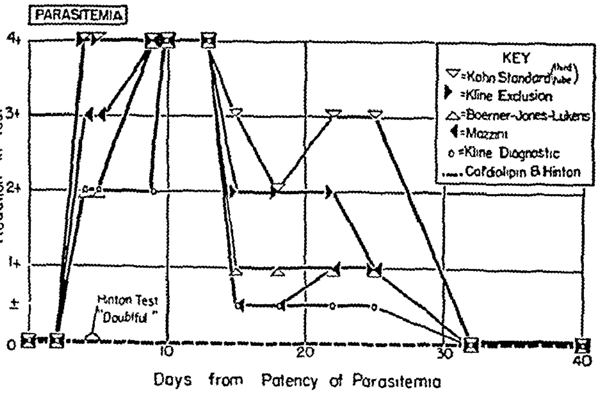
A Study of Their Incidence in Sporozoite-Induced Vivax Malaria

CHARLES R. REIN, M.D.
New York

and

CAPTAIN JOHN F. KENT
Sanitary Corps, Army of the United States

The disease malaria has been well established as one of the conditions which may produce a positive serologic reaction for syphilis in nonsyphilitic persons. Various investigations, however, have yielded data that varies widely as to the incidence of such false positive reactions. Excellent reviews of these studies have been published by Davis [1] and Beerman.[2]



Course of the serum reaction in seven tests for syphilis during an attack (third relapse) of sporozoite-induced vivax (St. Elizabeth strain) malaria.

An opportunity to reinvestigate the problem was afforded us two years ago when the United States Public Health Service initiated experiments concerned with the chemotherapy of sporozoite-induced human malaria. Our primary interest in obtaining specimens of serum from the subjects of these experiments lay in the development of a quantitatively standardized complement fixation test for malaria.[3] However, a concurrent study of the incidence of false positive reactions

in serologic tests for syphilis was also undertaken in view of the nature and scope of the experiments, which permitted the pretesting of a large group of selected persons before exposure to malarial infection and the examination of serial specimens of serum over extended periods of observation. We are indebted to Dr. G. Robert Coatney and his associates at the National Institute of Health, Bethesda, Md., for making several thousand serum samples available for our combined studies.

MATERIALS AND METHODS

Subjects for the experiments had been selected from male volunteers at the United States Penitentiary, Atlanta, Ga. Only those were enlisted who presented no clinical or anamnestic evidence of syphilis. Specimens of serum were obtained from each person before his inoculation with malaria by mosquito bite, at daily intervals during attacks, two or three times weekly after attacks and at weekly intervals through other periods, the total time of study lasting as long as eighteen months. The serums were preserved in tubes containing dried merthiolate sufficient to give a final concentration of 1.0 mg. per 1 cc. of serum. They were shipped by ordinary mail to the Army Medical School where they were subjected to a battery of serologic tests for syphilis which included the Kahn standard test, the Hinton flocculation test, and the Kline diagnostic, Kline exclusion, Mazzini, and Boerner-Jones-Lukens microflocculation tests. A newly developed microflocculation test[4] employing a cardiolipin antigen was included to determine its specificity in relation to the other procedures. A total of 7,493 serums obtained from 90 persons were examined in this manner; 44,958 serologic tests for syphilis were performed.

RESULTS

The present communication records the results obtained with successive serums from 90 persons. Of these, 80 had been infected with sporozoites of the well documented St. Elizabeth strain and 10 with sporozoites of the Chesson strain of Plasmodium vivax. Two types of primary attack were encountered. Early primary attacks occurred after the usual incubation period in untreated controls and in patients who had received experimental chemotherapy inadequate for suppression. Delayed primary attacks were experienced by subjects who had had a chemotherapeutic regimen adequate for suppression of an early primary attack. After primary attacks the subjects experienced from zero to six relapses.

A false positive reactor was defined as any person who developed a persistent reaction of degree plus-minus or greater after infection with malaria. Fifty-seven (63.3 per cent) of the 90 infected subjects developed such false positive reactions with one or more of the serologic tests at some time during the course of the disease. Forty-nine (61.3 per cent) of the 80 patients infected with the St. Elizabeth strain and 8 (80 per cent) of 10 patients infected with the Chesson strain fell in this group. In view of the small number of subjects infected with the latter strain, the observed difference in the frequency of false positive reactors is not considered to be significant. The relatively high incidence of false positive reactors observed in this study is considered to be due, in large part, to the frequency with which specimens were collected and to the number of tests employed in the serologic battery.

Seropositivity was not encountered in advance of the fever or parasitemia of an attack. False positive reactions appeared, on the average, 8.3 days following patency of the parasitemia, the interval varying in different persons within the limits, zero to thirty days. The observed average interval did not differ significantly in primary attacks and in relapses and appeared to be uninfluenced by the serologic test used. The accompanying illustration shows the course of the false positive reaction after an attack of malaria due to the St. Elizabeth strain of P. vivax. Reactions in this instance appeared four days after a parasitemia became patent. The Kahn standard and Kline exclusion tests showed the strongest nonspecific reactions, whereas the Hinton test yielded doubtful reactions over a two day period only. The mircroflocculation test employing a cardiolipin antigen was negative throughout.

In the great majority of subjects the nonspecific reaction was characteristically transitory and of low degree. False positive reactions which resulted from individual attacks of malaria persisted for intervals varying from a minimum of two to three days to a maximum of ninety-eight days. Reactions which persisted for longer periods were observed in certain instances when successive relapses supervened before the seropositivity due to a preceding attack had subsided. A maximum duration of five hundred and seventeen days was encountered in 1 such instance. It is noteworthy that, in general, the duration of such reac-

tions was influenced by two factors, (1) the specificity of the test employed and (2) the titer developed by the patient in question.

The determination of the specificity of the different serologic procedures was based on the percentage of patients developing persistent false positive reactions as previously defined herein. Separate analyses were made for each type of primary attack and for relapsing attacks in the order of their occurrence. The data are summarized in the accompanying table.

It will be noted that the incidence of false positive reactors appears highest in early primary malaria, somewhat lower in delayed primary attacks and lowest in relapses. Of the battery of tests employed in this study, the highest percentage of false positive reactors was observed with the Kahn standard test and the lowest with the Hinton flocculation test. The cardiolipin microflocculation test yielded results of exceptional specificity. It should be pointed out that the false positive reactors listed under the latter test in the accompanying table never gave reactions greater than plus-minus, whereas those listed for the Hinton test gave reactions ranging from doubtful to positive. The exceptional specificity of the Hinton flocculation and cardiolipin microflocculation tests is striking in view of their recognized high sensitivity in the serodiagnosis of syphilis.

SUMMARY AND CONCLUSIONS

In a controlled study of sporozoite-induced vivax malaria, a series of 7,493 serums obtained at suitable intervals from 90 nonsyphilitic volunteers were subjected to a battery of 7 serodiagnostic tests for syphilis; 44,958 tests were performed.

Fifty-seven (63.3 per cent) of the 90 infected subjects developed false positive reactions with one or more tests during the course of the disease.

The Hinton flocculation test and a microflocculation test employing a cardiolipin antigen yielded results of high specificity.

ABSTRACT OF DISCUSSION

DR. CHARLES R. REIN, New York: Dr. Giordano asked whether a complement fixation test was performed on these specimens. I should like to report that Captain Kent subjected most of these serums to several complement fixation procedures including the Kolmer test. The incidence of false positive eactions for syphilis was about the same as that obtained with ome of our flocculation tests.

At the Army Separation Centers some soldiers were found to have positive serologic reactions for syphilis without any clinical or anamnestic evidence of the disease. Many of these nonspecific or nonsyphilitic reactions were due to a malarial infection. We were able to subject the serums from some of these persons to a battery of serodiagnostic tests, including our new microflocculation procedure which employs a cardiolipin antigen. The characteristic serologic pattern obtained with such serums was a negative reaction with the cardiolipin test and doubtful or positive reactions with the other routine flocculation or complement fixation tests. In fact, whenever such a serologic pattern was obtained in our routine consultation cases, malaria was suspected and often proved to be the cause of the false positive reactions.

DR. BENJAMIN KLINE, Cleveland: Dr. Rein gave me some knowledge of his work with cardiolipin antigen, and the results in a series of 270 serums obtained from Crile Hospital bear out his findings. I had that number of serums in a series of some 9,500 covering general hospital and ambulatory cases, and a series of 650 serums in cases of unquestionable syphilis under treatment with penicillin. I have found in a comparison of present day standard antigens at their optimal concentration in one simple test, the flocculation slide test, that cardiolipin antigen can be set at a ratio that will give results as sensitive as those with Eagle and Mazzini antigens, for instance, and give more sensitive results than the Hinton, the Kahn and the Kline antigens. It is much more specific than any of the present day antigens. For instance, in the most important group, the malaria group, I found that whereas the tests with standard antigens averaged about 17 per cent false positive reactions, those with cardiolipin antigen varied from 1 to less than 2 per cent nonspecific reactions. In the state of Ohio physicians are reporting the results of tests with cardiolipin antigen and making it possible for young men returned from service, with no evidence of syphilis, to get married on the basis of the results with this remarkable, new antigen for syphilis.

DR. ALFRED S. GIORDANO, South Bend, Ind.: I wish to concur in the opinion expressed today on the specificity of the cardiolipin antigen in avoiding many of the false positive reactions. In my experience, while making this comparative study I was rather shocked to discover that, in addition to malaria and the other well known conditions in which false positive reactions have been found, there exists a high incidence of false positive Mazzini reactions in pregnancy and sepsis, particularly those associated with renal disease. This incidence is uncomfortably high, and the probable reason it hasn't come out is that in the national conferences such specimens were not included in the studies. In hospital practice, at least, these false positive reactions are frequently misinterpreted, and it is well to bear this fact in mind. With the return of the men from service, I have been aware of the false positive reactions of malaria, and whenever such reactions have been noted I have consulted with the physician, calling to his attention that in all probability the reaction was false and the patient should not be treated for syphilis.

PILONIDAL DISEASE—PRESENT STATUS OF MANAGEMENT

CURTICE ROSSER, M.D.
and
JACK G. KERR, M.D.
Dallas, Texas

General agreement has been reached concerning the mechanics involved in the embryonal development of the various postanal cysts and sinuses usually grouped under the general term "pilonidal disease." The theory that these are due to epithelial sequestration has taken complete precedence over all previous suggestions linking the condition with preen glands or medullary outgrowths. There is no such unanimity, however, in regard to the proper surgical treatment, and the purpose of this paper is to summarize and review present opinion on this moot subject.

It has often been said that wars offer an opportunity for mass experimentation in the management of disease, and this has been especially true during World War II in relation to pilonidal disease. Thousands of patients have been operated on by various technics with emphasis on closed surgical procedures. In the last few years a number of articles on the subject, almost entirely from military sources, have appeared in medical literature.

In general, a comparison of the articles published during recent years with earlier writings on this subject impresses one with the apparent acceptance of two major premises. One, that trauma, while unrelated to etiology, is a factor in the development of clinical symptoms; and second, that surgical intervention is the treatment of choice. In no report on the experiences

gained during military service have we seen advocated, as a method of eradication of the disease process, any of the several ambulatory methods described earlier. Also, the thesis is developed that military requisites demand a method of treatment that rehabilitates and returns a soldier to military duty as quickly as possible, since there is little space available for prolonged hospitalization and no provision for extended convalescence. Hence the procedures acceptable in civilian practice, such as block excision and allowing the resultant wound to heal by granulation during an extended ambulatory period, had to be supplanted if at all possible. With this objective certainly any one would agree. However, this criterion, as it relates to the time required for postoperative healing, has never demanded the attention that it did in military circles, since most civilian patients are allowed to resume their usual activities ten to fourteen days after block excision and open packing, whereas a soldier with an unhealed wound must be a hospital patient. This point is brought out in almost every report of war time experience, with the resultant emphasis being given to a method of handling the wound, both preoperatively and postoperatively, that lessens the duration of morbidity, allowing the percentage of "cures" to fall where it may.

Of course few, if any, of the recently advocated methods of dealing with the condition are new in their entirety. Many reviews prior to the war era have discussed various methods of complete excision followed by primary closure of the wound with and without drainage, excision with partial closure of the wound, excision followed by open packing of the wound, partial excision of the cyst wall with marsupialization as described by Buie[1] and various plastic procedures utilizing additional cutaneous incisions as described by Lahey.[2] Based on rates of recurrence only, opinion prior to the war was definite that some type of open operation was far superior to any type of closed procedure. Kleckner[3] substantiated this in 1936 when, after a poll of many proctologists, he found that open operation performed on 4,231 patients yielded a recurrence rate of 1.3 per cent, while this rate was 23.29 per cent after operations with primary closure of the wound.

Rogers,[4] reporting in 1933 on 119 cases of pilonidal sinus from the Massachusetts General Hospital during the years 1924 to 1931, found the incidence of recurrence to be: 36 per cent when primary suture of the wound was performed; 50 per cent in partially closed wounds, and 18 per cent if the wound was left open following excision. Subsequently, Rogers and Dwight[5] reported only 2 failures in 140 cases in which open packing of the wound was employed. Further, they advanced the conclusion that the cause of failure was usually not incomplete removal of the sinus epithelium but, rather, the newly formed epithelium in the process of faulty healing.

Swenson, Harkins and Groesbeck,[6] following Rogers' technic of open packing, reported 2 failures in 32 cases, with an average healing time of 14.4 weeks. They also emphasized the importance of close observation during the entire postoperative period and in particular during the final weeks.

The foregoing reports, while by no means exhaustive, do represent a fair estimate of the preponderance of opinion in favor of the so-called open operation, as it was expressed prior to the more recent military experiences. From these it will be noted that little emphasis was placed on the necessity for a reduction of the time required for the postoperative healing of the wounds, but stress was given to the ultimate complete recovery of the patient after some period of follow-up. In contrast, practically all the reports by medical officers on their experience while in service favor and advocate some attempt at closure; these recommendations appear to be approximately equally divided between methods of partial closure and complete primary suturing of the wound.

Brockbank and Floyd,[7] advocating marsupialization, expressed the belief, after their observation of 168 consecutive cases of pilonidal disease, that 90 per cent of patients can be returned to duty, completely healed, in twenty-one to twenty-eight days.

Coffey[8] has reported handling 50 cases by the same method without recurrences. He employed this method in 6 cases while in service on a battleship, with an average of twenty-one days lost from duty.

Mutschmann and Mitchell[9] stated that in their experience primary closure did not prove satisfactory and open packing required too long a period of healing. They advocated allowing acute infection, if present, to subside after adequate drainage; then, after block excision, the skin edges should be sutured to the sacrococcygeal fascia, leaving the skin edges apart without tension.

A somewhat radical departure from the common custom of performing surgical intervention aiming at cure only after the complete subsidence of the acute inflammatory process, is that advocated by Peterson and Ames.[10] They employed a method of marsupialization with no period of preoperative preparation, operating on patients with acute cases of the disease even in the presence of heavy infection. The edges of the skin are sutured to the edges of the cyst wall with steel wire, which is removed in seventy-two hours. They have reported the treatment of 75 to 100 patients with an average time on the hospital ship of between three and four weeks.

Striking among the reports are some that advocate complete excision of the disease process followed by complete primary closure of the wound. Formerly, this type of procedure led to many failures of primary union of the wound as well as to subsequent draining sinuses and recurrent abscesses, which, as some have suggested, may have infrequently been the result of incomplete removal of cyst epithelium, but rather were due to lack of the attention apparently necessary for the success of this procedure. Woldenberg and Sharpe[11] reported 100 consecutive patients from an Army hospital who were treated by excision and primary closure. Eighty per cent had draining sinuses on admission. The incidence of recurrence in these cases was 2 per cent with an average time of healing of 21.5 days and a return to full military duty in an average of 28 days.

Shute, Smith, Levine and Burch[12] reported 59 cases in which complete closure of the postoperative wound resulted in complete primary healing in an average of eight days in 48 instances. There were postoperative complications in the remaining 11 cases, but these healed in an average of twenty-two days. Eleven days was the average healing time of the entire series of 59 patients.

Byrne[13] has reported that 20 of 23 patients treated by excision and complete suture of the wound had primary healing in seventeen days. The average time of healing was sixteen days; the longest time required for completion of healing was thirty days.

Bartlett[14] has strongly advocated primary closure, stating that methods of partial closure, such as marsupialization and suture of the skin to the sacrococcygeal fascia, require far longer periods of healing than do successful primary closures. If these methods are to be taken as routine forms of treatment it is necessary to assume, according to Bartlett, that: (1) there is no practical alternative to prolonged disability in order to assure cure; (2) the final result will be satisfactory in a high percentage of cases after such procedures, and (3) excision and primary closure, while ideal, cannot be accomplished with great regularity. In his report he has based his opinion on 20 cases with complete suture of the wound, 18 of which healed primarily.

Alley and Richey[15] reported 86 closed operations, in which all but 5 wounds healed by primary union. The period of hospitalization was prolonged in these 5 cases to an average of fifty-four days; however, the average number of postoperative days for the entire group was 26.5 days, including those with delayed healing time. Further, Alley and Richey reported that from a total of 85 operations for pilonidal disease, they were able to close 78 by primary suture.

Larkin,[16] in perhaps the most recent report of a large number of cases of pilonidal disease, based on experience while in military service, reported complete healing in seven days postoperatively in 90.9 per cent of 66 cases in which no previous surgical intervention had been performed. In 21 cases in which previous surgery had been done, 71 per cent only had primary healing. The average healing time in his series of cases was 26.5 days.

To supplement the published literature on this subject and to obtain the considered opinion of a group of proctologists whose work before the war included surgical experience in the management of pilonidal disease capable of serving as a basis of comparison with their own military observation, a questionnaire was addressed to thirty-five rectal surgeons who served in World War II. A brief expression was requested on present opinion in regard to the open or closed type of procedure in civilian practice together with any preference for a special technic in either case.

As has been stated, military and civilian surgeons are influenced by varied considerations, including regulations as to hospital stay and the type of duty to which the patient must be returned after discharge from the hospital. It was for this reason that nonmilitary conditions were specified in the questionnaire, and the questions were designed to secure the considered reactions of those who for the most part have now returned to private practice.

Twenty-seven answers were received; some of those who did not submit replies stated that their military service failed to include proper experience in this connection. Twenty-one of those who replied (77.7 per cent) now regard the open type of operation as the best standard procedure under the conditions stipulated. Five (18.5 per cent) believe that various closed procedures which were developed in military service will be routinely satisfactory in private practice, and one, Dr. Robert A. Scarborough,[17] while stating that "Block excision with primary closure is the procedure of choice," sets up certain exacting criteria, in the absence of which he prefers open excision with immediate skin grafting.

A few of those who favor the open type of operation still feel that a return to routine classical complete excision of the lesion associated with saucerizing of the wound and few if any sutures is desirable. Those who take this position[18] feel that while primary closure may have been justifiable in soldier personnel in order to return those whose wounds healed to duty as quickly as possible, the results were not uniformly satisfactory, the published reports did not always include sufficiently lengthy follow-up statistics and the classical procedure is dependable as to freedom from recurrence and will be satisfactory in civilian practice. A number of those who favor open procedures for the majority of cases have become convinced, however, that under certain specified conditions the wound may well be closed at the time of operative intervention. Dr. Neil W. Swinton,[17] for example, believes that for the clean pilonidal sinus in the midline in an intelligent patient who is willing to spend twelve days in the hospital, excision and primary closure is justifiable; and Dr. Tom E. Smith,[17] while also convinced that the open operation is the only surgical procedure which can be used without fear of recurrence of symptoms, states that if the last episode of infection has occurred at least six months before the operative intervention the surgical technic devised by Shute[12] will frequently be satisfactory. Several other answers[19] stress conclusions that various closed procedures, while ideal from the theoretic point of view were disappointing in cases in which any remnant of infection was present, which may explain the sweeping "directives" which finally prohibited radical procedures in several of the hospital services. In cases of this type the wounds appeared to have been well healed but shortly after the discharge of the patient from the hospital they separated because of the fact that healing beneath the skin surfaces was not secure. For that reason this group[19] would restrict the closed type of operation to a few selected cases.

A surprisingly large number of answers expressed satisfaction with the open procedure by which the lesion is marsupialized. Several[20] used the technic devised by Buie.[1] Swinton[17] incises the involved area with an electrosurgical unit removing a minimum amount of skin and lays open the underlying sinus tract, after which the wound is packed with petrolatum gauze; Dr. John C. M. Brust[17] opens the cyst, scrubs the bases with gauze, exposes all tracts and bevels the wound. No sutures are used, and the wound is packed with dry gauze under pressure. Those who have adopted marsupialization certify that the wounds heal by granulation with few complications and that a minimum of cicatrix remains. Dr. Raymond L. Murdoch[17] destroys the lining of the tract superficially.

Dr. Charles E. Pope[17] has devised a new procedure featuring a sliding gluteus maximus muscle graft by which the avascular fascial plane is covered and dead space is obliterated; he favors a closed procedure in all cases if this is done. Dr. Lester J. Johnson[17] completely excises all tracts, loosens the gluteal fascia to permit approximation without tension and uses wire for all sutures. Dr. Rufus C. Alley[17] is strongly committed to excision and primary closure in suitable cases but believes that the simplest operation is the most satisfactory. He does not favor undercutting or buried sutures, and the closure is done with stainless steel wire. Drs. Victor C. Tucker[17] and Clyde L. Wilson[17] also prefer primary closure after infection clears.

COMMENT

From these reports it is readily seen that those who advocate primary complete closure of wounds after the excision of pilonidal cysts and sinuses make a strong point in their favor. They demonstrate beyond any question that many man days can be saved during the convalescent period. On this basis, certainly, the procedure can be justified so far as it applies to the armed forces and in all probability would have far more advocates among those doing civilian practice, if, as in the Army and Navy, patients were not permitted to resume their normal activity but were obliged to remain hospitalized until healing of the wound was complete. This perhaps would be true even at the expense of an added risk of "recurrence" as compared with the so-called open operation.

The incidence of poorly healed wounds, as reported by those advocates of primary closure cited herein, compares most favorably with many reports of preference for the more conservative approach of excision and open packing.

As Barnett[21] stated, military requisites being as they are, the recently developed technics of excision and primary closure of selected cases offer the best solution to the problem; but the more conservative method of excision and open packing is indicated in many cases not amenable to radical surgical intervention and is the procedure of choice in civilian practice.

One should not pass from a discussion of the closed procedure without emphasizing a point repeatedly cited by adherents of primary closure. Success is wholly dependent on fundamental surgical principles, including complete obliteration of all dead space, meticulous hemostasis and sufficient mobilization of tissue to avoid tension on sutures. In regard to other points of technic, such as the type of suture material, the use of sulfonamide preparations and penicillin and the employment of pressure dressings, some leeway would seem permissible. As suture material, fine catgut, cotton and stainless steel wire each has its advocates.

The local application of a sulfanilamide drug is commonly employed, although the comments of Burch[12] and associates regarding its use are interesting. In their first 29 cases a buffered sulfanilamide was used which seemed to cause oozing and the accumulation of serum in the wounds. Nine of their 11 complications were in this group.

Our own civilian experience with an operation including complete excision of diseased tissue, no sutures except (in larger wounds) a simple inversion of the skin edges and a rubber covered pack has been sufficiently satisfactory that we have not heretofore been tempted to adopt closed procedures. Within the past eighteen months, for example, our own patients on this type of surgical management have spent an average of six days in the hospital, have been away from work an average of fifteen days, and have had all wounds healed firmly and without recurrence in an average period of six weeks and one day.

It would be unwise, however, to neglect fair consideration of the studies which have been made by military surgeons, and these definitely indicate that there will be a place in civilian practice for marsupialization and for the reconstructive primary closure of pilonidal wounds when properly indicated and properly performed.

710 Medical Arts Building.

ABSTRACT OF DISCUSSION

Dr. Walter A. Fansler, Minneapolis: Since I saw numerous recurrences of pilonidal disease in patients operated on by the closed method in both the Army and Navy, I am more than ever convinced that operation by any closed method should be limited to a small number of patients. This paper demonstrates the fact that there is no unanimity of opinion as to what is the best type of operation. There has been a rash of papers, as Dr. Rosser pointed out, on pilonidal disease, and a great many of them were published, of course, by men in the armed forces. I do not believe that there has been too much contributed by these papers in the way of permanent conclusions concerning pilonidal disease. In most instances an insufficient time has elapsed following the operations before the papers were published. It takes months to be sure of the results after an operation for pilonidal disease, and in isolated instances there may be recurrence years later. This time lack was, of course, unavoidable under existing circumstances. Many of the soldiers and sailors were transferred to other camps or to active duty elsewhere, or the medical officer was transferred. I am convinced, particularly in civilian practice, that, primary closure is seldom to the best advantage of the patient. The hospital time and expense, the period of disability, the loss of time from work and the chances of recurrence are all far greater than where the open method is used. By the open method, with proper regard for a few fundamental principles and proper postoperative supervision, cure without further surgical intervention will almost uniformly result. That healing time is longer is not denied, but hospitalization and actual loss of time from occupation is less. There are but three fundamental causes of failure to cure this disease by the open type of operation: (1) failure to remove all of the tract; (2) failure to leave the right type of wound for healing, and (3) improper attention to postoperative care. The wound which is left must be flat. If a deep, well-like wound with steep sides is left, failure will result in many cases. In thin persons the wound is naturally flat. I think most of us have observed that the difficulty in healing occurs usually in fat people who have a deeper intergluteal fold or cleft. In them this flattened condition must be produced surgically. This is accomplished by removing a generous wedge of fat from both the sides and the ends of the incision. I emphasize at the end of the incision, because that is often not done. Laterally it is often necessary to denude the fat down to the gluteal muscles. No skin should be removed other than the diseased margins

---

21. Barnett, L. A.: Pilonidal Cyst, Am. J. Surg. 64: 338-345 (June) 1944.

about the openings of the sinus. After the fat has been removed the resultant skin flap is brought toward the base of the wound and stitched to the fascia covering the sacrum. This can be done by either continuous or interrupted sutures. The sutures are placed as near the midline as possible, without making undue tension on the skin flaps. This leaves but a narrow wound to heal by granulation. A pressure dressing is applied to hold the flaps in close apposition to the underlying tissues and to aid in preventing the formation of hematoma. The recent suggestion of Larkin, as to the use of a sponge rubber pad for this purpose seems excellent. In the postoperative care two conditions must be guarded against. The wound must not be allowed to bridge over too quickly. Since the wound is flat, rather than deep and trenchlike, the prevention of this condition is seldom much of a problem. Second, there may be a tendency at the ends of the wound for the skin to heal too rapidly. This produces a small pocket, and if this occurs the skin must be snipped longitudinally; otherwise healing may be delayed or a small sinus may result. This complication can often be prevented if, at the time of operative intervention, a small triangular section of skin is removed at either end of the incision.

Clinical Notes, Suggestions and New Instruments

TETANY FOLLOWING MERCURIAL DIURESIS

FRANK A. MARSHALL, M.D.
Weehawken, N. J.

Carpopedal spasm, which results from a lowering of blood calcium incident on diuresis following repeated administration of mercurial diuretics over a long period, has not been specifically reported in American medical literature. Such a possibility has been strongly suggested recently in a reply in The Journal of the American Medical Association to a query[1] on "Muscle Cramps Following Mercurial Diuretics." The subject is dismissed with the notation that "at times, loss of calcium in the urine may be excessive and a trial of calcium gluconate, intramuscularly or intravenously, shortly before the diuresis is initiated may be effective."

Several reports of cases have appeared on this subject in foreign medical literature. The case of Pavel and others[2] closely parallels the present one. Both patients were subject to long continued and repeated injections. In both cases blood calcium was approximately 7 mg. per hundred cubic centimeters after injection.

In the second case occurring abroad,[3] Sendel reports a fatal issue in an edematous Hindu infected with ancylostoma. Typical carpopedal spasm and laryngismus developed immediately after the injection, despite the use of 2 cc. of colloidal calcium and the oral administration of 2 Gm. of ammonium chloride two hours previously. Five minutes after injection of the mercurial (Neptal, an addition product of mercury acetate and salicylaminoallylacetic acid) the patient expired. This case differs from Pavel's and the appended one in the time elapsing after the injection. Time for diuresis was not available; hence, the effect of a massive outflow could not have been causative in Sendel's patient, who died following his second injection of a mercurial. Malnutrition and chronic hookworm infestation may have contributed to this explosive fatal result. This case may explain one of the modes of exitus following injection of these mercurials.

Nothmann[4] observed a lowering of serum calcium in some cases in 1933.

The emphasis in American literature[5] has been on the loss of chlorides (10 per cent or more of serum chlorides) with the use of ammonium chloride as the therapeutic agent. Muscular cramps are referred to as "similar to heat cramps," which may be in error if closer examination of the patient is made. The present patient referred to her pains as "cramps" when she was observed with typical carpopedal spasm.

REPORT OF CASE

History.—Mrs. E. K., a moderately obese woman aged 60, was seen in her home over a period of five months for congestive failure, hypertensive heart disease and emphysema. On May 17, 1946 she appeared flushed, cyanotic and dyspneic, with a blood pressure of 200 systolic and 96 diastolic; the pulse rate was 85. Significant past history revealed that a thyroidectomy had been performed in Switzerland in 1931 for a probable substernal goiter, as the patient "couldn't catch breath" prior to the operation because the mass "squeezed on breathing pipe." She was treated in 1935 for bronchial asthma and hypertension. To secure relief from dyspnea, she sojourned to Arizona in 1935. In 1943 the first mercurial was injected. These intramuscular injections now total over two hundred. As a result, both buttocks are considerably indurated. When a needle is inserted into them, the fibrous, hard nature of the subcutaneous and muscular tissue can be noted. Veins in her arms are not palpable or visible, partly as a result of obesity and partly from previous attempts to give intravenous medication (theophylline ethylenediamine, epinephrine and the like). Tetany was never experienced following thyroidectomy.

Physical Examination.—Physical examination reveals an extremely hypersensitive patient who readily jumps when touched. The scar of the previous thyroidectomy is barely visible. Thyroid masses are not observed. The veins of the neck are distended, even in a semiupright position.

The skin, particularly that of the neck, is flushed and cyanotic. The lungs are emphysematous. There are dulness and diminished breathing posteriorly at the base of the right lung. Wheezing is heard anteriorly over the chest on both sides.

The apex beat is not felt, but heart sounds are best heard in the axilla, where they sound muffled. The rhythm is regular with a rate of 85 per minute. Adventitious sounds are not heard. In the abdomen, shifting dulness is not noted. The liver is enlarged to six fingerbreadths below the costal margin, which is tender yet smooth. Sacral pitting edema (++) and dependent edema (+++) over both legs is present. The eyes are flushed. Retinal sclerosis is present. The disks are normal. Neither hemorrhage nor exudate is noted.

Laboratory Data.—Laboratory reports are as follows: Urinalysis indicated 3 plus albumin; reaction acid; specific gravity 1.026; white blood cells 1 plus; red blood cells 2 plus, and epithelial cells 3 plus. The rest of the urinalysis is within normal limits.

Examination of the blood reveals: sugar 125 mg., creatinin 1.8 mg., nonprotein nitrogen 35.5 mg., urea 16.1 mg., calcium (April 24, 1946) 7.4 mg. and phosphorus 5.5 mg. per hundred cubic centimeters.

Electrocardiographic tracings indicate that the P_1 is isoelectric, the P_2 and P_3 inverted, the PR interval 0.16 second, the QRS complex 0.07 second, the QT interval 0.40 second, with an auricular and ventricular rate of 80 per minute. The T waves in leads 1, 2 and CF_4 are inverted. The CF_2 lead has a diphasic T wave. The QRS complexes in leads 1, 2 and 3 are slurred. The ST_1 interval is depressed 1.5 mm.

Present History.—The patient has been digitalized and continued on maintenance doses of digitoxin with 0.4 mg. on one day and 0.2 mg. on the next. Theophylline ethylenediamine, phenobarbital and pentobarbital sodium have been given as required. Insomnia is one outstanding complaint. One evening the patient took 9 grains (0.58 Gm.) of Seconal sodium without any benefit. Recurrent episodes of congestive failure and nocturnal dyspnea have been frequent for the past five months, responding only partially to treatment. An annoying symptom has been vomiting, which occurs in spells. Mercurial diuretics (mersalyl and mercurophylline injection chiefly) have been given at intervals of three to ten days as required by edema and congestive failure.

[5] Cattell, McK., in Treatment of Edema by Drugs, Conferences on Therapy, New York State J. Med. **44:** 280 (Feb. 1) 1944. Footnote 1.

Tetany Episode.—On April 18, 19 and 20, vomiting was in abeyance. On April 21, the patient vomited slightly at 5 a. m. following the ingestion of 15 grains (0.97 Gm.) of enteric coated ammonium chloride. On Monday, April 22, she appeared better than usual, without extraordinary presenting symptoms or signs except edema (++++) of the legs. Mercurophylline, 1 cc. (Mercupurin) was injected at 10:15 a. m. into the left buttock intramuscularly. At 11:15 a. m., and prior to diuresis, the patient felt a "tightening" in her toes. A large quantity of urine (quarts—but she failed to measure amounts) was passed between 2 and 5 p. m. Spasms in the feet, severe by now, increased considerably in intensity. When I was summoned to see the patient at her home at 9:25 p. m., somewhat less than twelve hours following the injection, typical tetany was present with carpopedal spasm distinctly evident bilaterally. Adducted thumbs could be abducted only with considerable effort and with pain to the patient. Severe cramps and spasms in the leg muscles, in addition to flexion of the toes, were present. Laryngospasm and diffuse abdominal pain were evident. The Chvostek sign could not be elicited. Extreme hyperexcitability of the neuromuscular system was noted; muscular spasmodic contractions resulted on merely touching the patient lightly.

Calcium gluconate, 10 cc. of a 10 per cent solution, was administered intramuscularly. Orally, ten wafers, each containing dicalcium phosphate (9 grains, or 0.58 Gm.), calcium gluconate (6 grains, or 0.39 Gm.) and vitamin D (666 units), were given as soon as the patient could swallow them. Morphine sulfate (¼ grain, or 0.015 Gm.) was given to alleviate pain and restlessness.

On the following day, April 23, the administration of 10 cc. of 10 per cent calcium gluconate (1.3 grains, or 0.08 Gm.) was repeated by intramuscular injection both in the morning and in the evening. Tetany was subsiding by the next morning and disappeared by that evening. Ill effects from the parenteral administration of calcium were not observed, in spite of digitalization. The electrocardiogram had shown typical ST deviation characteristic of the action of digitalis.

On April 24, in spite of the ingestion of calcium wafers and the use of parenteral calcium to relieve tetany, the blood serum calcium was only 7.4 mg. but the serum phosphorus was 5.5 mg. per hundred cubic centimeters. The blood pressure was now 198 systolic and 96 diastolic, as compared with 214 systolic and 120 diastolic on the previous day.

On April 29, recurring edema and clinical interest suggested another trial with a mercurial diuretic. A solution of 1 cc. of mersalyl theophylline (0.1 Gm. mersalyl and 0.05 Gm. theophylline) was injected into the right buttock at 11 a. m. Vomiting had not occurred for several days previously, nor was there any dyspnea. Four quarts (3,785 cc.) of urine were passed after the injection. At 9 p. m. the patient noticed spasms (cramps) in her feet which lasted throughout the night. She ingested calcium wafers at 10 p. m. She stated that considerable relief was experienced on gently rubbing the calves of the legs with alcohol.

On May 7 at 11 a. m., injection of 1 cc. of mersalyl and theophylline was repeated because of edema of the legs and other signs of congestive failure. Three quarts (2,839 cc.) of urine were passed. At 11 p. m. tingling of the fingers, tensing of the toes and severe cramp in the muscles of the right calf, which was felt by the examiner, was relieved by the ingestion of five wafers of dicalcium phosphate and calcium gluconate, the injection of morphine and the application of alcohol to the legs.

Subsequent injections of mercurials have not produced any definite signs of tetany. The patient continues on milk and takes her wafers of calcium as she pleases. She is hyperexcitable and jumps readily when touched.

COMMENT

The occurrence of evidences of tetany on three separate occasions in this patient following the parenteral use of mercurial diuretics stresses the need for thought on the mobilization and excretion of electrolytes other than the chlorides, although the latter continues to be among the most important. Gratifying relief in this case was obtained through the use of parenteral and oral calcium. Blood calcium levels were reduced following the attack to about the same level as that reported abroad in another case. It appears that tetany is more likely in patients who may ordinarily have a borderline deficiency, which is further reduced below this critical level by excessive diuresis.

The use of parenteral and oral calcium in moderate doses lacked deleterious effects in this fully digitalized patient.

On the occasion of the first tetany reaction, it was observed that this patient had signs of tetany prior to the excessive diuresis. Sendel's patient, who died five minutes after receiving an intravenous injection of a mercurial, displayed signs of tetany without any preceding diuresis. These observations suggest some mechanism other than profuse diuresis as a cause for electrolyte imbalance. Possibly the normal interstitial fluid and its electrolytes surrounding the muscle fibers, including cardiac muscle, are mobilized and reduced too rapidly, causing symptoms.

CONCLUSION

1. Tetany that followed the injection of diuretic mercurials and recurred on three separate occasions was relieved by the administration of calcium. The patient showed a low blood calcium level.

2. Over two hundred injections have been given to date in a period of three years to this patient.

3. Signs of electrolyte imbalance may be in evidence prior to diuresis. Some mechanism other than the diuresis is probably operative.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

EASTMAN RADIANT ENERGY LAMPS ACCEPTABLE

Manufacturer: The J. H. Eastman Company, 1304 Harper Avenue, Detroit 11.

The Eastman Radiant Energy Lamps, models 260 and 375, are infra-red generators. The lamps may be used for administering local radiant heat for therapeutic purposes. According to the firm, the power required for model 260 lamp, serial #535, at 120 volts is 260 watts and for the model 375, serial #415, at 120 volts is 375 watts.

The firm submitted a report demonstrating the ability of the Eastman Radiant Energy Lamps, models 260 and 375, to produce "deep heat." The technical procedure used in making the tests was that recommended by the Council on Physical Medicine of the American Medical Association (The Journal, April 20, 1935, p. 1413) for obtaining the temperature rise in deep muscle tissue. The result obtained when using either model showed that 0.8 degree F. was the average temperature rise in the deep tissues of the thigh with twenty minute applications. Blistering was noted on the second heat application in the series of tests. Precautions should be taken against overheating and the lamp-skin distance adjusted accordingly. By using special filters the firm claims that the long wave infra-red rays are filtered out. Experimental data supplied by the promoter fails to substantiate this statement.

While the apparatus is acceptable as a source of infra-red radiation for local heat, the firm has not shown that the lamps are more efficacious therapeutically than a conventional infra-red lamp equipped with an ordinary tungsten filament bulb.

The Council voted to include the Eastman Radiant Energy Lamps, models 260 and 375, in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.

AUSTIN SMITH, M.D., *Secretary.*

STATUS REPORT ON OINTMENTS CONTAINING ESTROGENIC SUBSTANCES

A drug manufacturer recently submitted to the Council a cream the chief active constituent of which was an estrogen. The product as marketed by the firm concerned was to be sold only on prescription. The use of such preparations has been the subject of considerable investigation, but on the basis of the existing evidence it would seem that there is need for much more work before this technic of application of an estrogenic substance can be generally adopted. The effective dosage obtained following the topical application of an estrogenic substance would be highly unpredictable owing to differences in absorption through the skin. There does not yet seem to be available data that would justify a belief that the local administration of estrogenic substances may be as satisfactory as other routes of administration.

From time to time there appear reports of the misuse of such preparations, especially when they fall into the hands of individuals unqualified to judge the needs of their bodies. When such possibility, or probability, exists the packages containing such preparations should bear adequate warning of the dangers involved in their use. The Council has previously published a report on cosmetics containing hormones (THE JOURNAL, June 16, 1945, p. 515) and has pointed out some harmful possibilities that may exist. Until more evidence is accumulated, the Council is of the opinion that the use of creams or ointments containing estrogenic substances seems unpromising on the basis of present available data and should be reserved for those qualified to evaluate properly the results that may be obtained following the use of such preparations.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

HEPARIN SODIUM.—The hydrated sodium salt of a naturally occurring, complex organic polymer possessing anticoagulant properties. The chemical structure of heparin has not been fully established. It is considered to be a dextrorotatory polysaccharide made up of hexosamine and hexuronic acid units containing sulfuric acid ester groups. Heparin is found in a large number of body tissues. Heparin sodium may be prepared from liver or lung tissue by a modification (Kuizenga and Spaulding: *J. Biol. Chem.* **148**:641, 1943) of the method of Charles and Scott (*Biochem. J.* **30**:1927, 1936). The product is further purified for medicinal use.

Heparin sodium is standardized to possess not less than 100 units of anticoagulant activity per milligram of dry material, by the sheep plasma coagulation method (Kuizenga, Nelson and Cartland: *Am. J. Physiol.* **139**:612, 1943). The standard of potency is the Provisional International Standard, a dried preparation of the sodium salt of heparin to which has been assigned a potency of 130 units per milligram (*League of Nations, Bulletin of the Health Organization,* Vol. X, No. 2, p. 151, 1942-1943). This Provisional International Standard is to be used only as a standard of potency.

Actions and Uses.—Heparin sodium has the property of inhibiting blood coagulation. It may aid the normal body to maintain blood in a fluid state as traces are detectable in the blood. Very little is known concerning the metabolism, excretion and fate of heparin sodium in the body. Its anticoagulant action appears to be effected by action on the thrombin, which with fibrinogen forms fibrin.

The exact status of heparin sodium in surgery and medicine has not been determined, but it is claimed to be of value as a substitute for citrate in blood transfusions, in an attempt to prevent postoperative thrombosis and possibly thrombosis of other origin, the prevention of recurring thrombosis in phlebitis and pulmonary embolism, and other uses. It has been used alone and with sulfonamides in the treatment of subacute bacterial endocarditis, but much work remains to be done before this procedure can be generally accepted; results have not been impressive.

Dosage.—The potency of heparin sodium is expressed in units. Ampul solutions keep indefinitely and may be sterilized by boiling or autoclaving at 110 C. for thirty minutes. The substance is inactive orally and is usually injected intravenously. It may be given by single injection or continuous intravenous drip, the infusion being adjusted by watching the coagulation time. The clotting time should be maintained between fifteen and twenty minutes. If a chill develops or spontaneous bleeding occurs, the drug should be stopped. When the interrupted dose method is employed, 50 mg. (5,000 units) may be administered at intervals of four hours up to a total of 250 mg. per day. For continuous drip, 100 to 200 mg. (10,000 to 20,000 units) is added to 1,000 cc. of 5 per cent sterile dextrose or isotonic sodium chloride solution. The flow may be started at about twenty drops per minute.

Tests and Standards.—

Heparin sodium occurs as a white to lightly colored, amorphous, gumlike powder. It is very soluble in water but practically insoluble in alcohol, acetone, benzene, chloroform and ether. The *p*H of a 1 per cent solution of heparin sodium lies in the range 6 to 7 at 25 C.

Place 5 cc. of 0.005 per cent toluidine blue O solution (made by dissolving 25 mg. of toluidine blue O in 500 cc. of water containing 1 cc. of diluted hydrochloric acid) in a test tube, add 5 cc. of water and 1 cc. of 1 per cent heparin sodium solution: the color of the mixture changes from blue to reddish blue; add 2 cc. of petroleum ether and shake the mixture vigorously for one minute. Allow the emulsion to break: the color of the solution returns to pale blue and a purple precipitate collects in the interface between the liquids.

Place 1 cc. of 1 per cent heparin in a test tube; add 2.5 cc. of *o*-phenanthroline ferrous complex solution (U. S. P. XII, p. 739): a red precipitate forms.

Fuse about 50 mg. of heparin sodium with a small piece (2 cmm.) of metallic sodium in a test tube; cool, add 5 drops of ethanol, leach the fused mass with 5 cc. of water and filter: the filtrate responds to tests for cyanide and sulfide, indicating the presence of nitrogen and sulfur respectively.

Add 1 drop of ammonium hydroxide solution and 3 drops of 30 per cent hydrogen peroxide solution to 0.5 cc. of 1 per cent heparin sodium solution contained in a test tube. Heat on a water (steam) bath for ten minutes: no cloudiness results which cannot be cleared by making the solution acid to congo red, by the addition of just sufficient diluted hydrochloric acid (*barium ion*).

Mix 5 cc. of 1 per cent heparin sodium solution with 5 cc. of sulfosalicylic acid reagent (dissolve 20 Gm. of sodium sulfate decahydrate in 80 cc. of water, cool to 35 C., add 5.0 Gm. of sulfosalicylic acid, dissolve and dilute to 100 cc.). Heat the mixture to boiling; no cloudiness should be discernible (*protein*).

Ash 0.1 Gm. of heparin sodium in the presence of sulfuric acid in a tared porcelain crucible: the sulfated ash amounts to not more than 40.5 per cent of the dried substance.

Dry about 0.1 Gm. of heparin sodium for twenty-four hours at room temperature over phosphorus pentoxide in a vacuum desiccator at a pressure not above 5 mm. of mercury: the loss in weight is not more than 12 per cent.

Heparin sodium shall meet the pyrogen test described in the U. S. P. XII when solutions containing 1,000 units per cubic centimeter are injected in a dosage of 2.0 cc. per kilogram of body weight.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Solution Heparin Sodium: 10 cc. vials. Each cubic centimeter contains 10 mg. of heparin sodium, preserved with 0.5 per cent phenol.

UPJOHN COMPANY, KALAMAZOO, MICH.

Solution Heparin Sodium: 10 cc. vials. Each cubic centimeter contains 10 mg. of heparin sodium, preserved with 0.5 per cent chlorobutanol.

SODIUM ASCORBATE (See New and Nonofficial Remedies, 1946, p. 633).

The following dosage form has been accepted:

WILLIAM H. RORER, PHILADELPHIA

Solution Sodium Ascorbate: 100 mg. in 1 cc. ampuls. Each cubic centimeter contains sodium ascorbate equivalent to 100 mg. (2,000 international units) ascorbic acid and thiourea 0.01 per cent in sterile aqueous solution.

PENICILLIN IN OIL AND WAX (See the Supplement to New and Nonofficial Remedies, 1946, p. 15).

The following dosage form has been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Penicillin (Calcium) in Oil and Wax: 1 cc. syringes or 5 cc. vials, 300,000 units per cubic centimeter.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1946, p. 618).

The following dosage form has been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Tablets Thiamine Hydrochloride: 5 mg. and 10 mg.

THE ATLANTIC CITY SESSION

In the Organization Section in this issue of The Journal appears an announcement relative to the General Scientific Meetings to be held in connection with the Atlantic City session, June 9-13. The programs of the General Scientific Meetings provide for discussions of subjects of special and timely interest to the medical profession and for panel discussions of the modern management of heart disease, emergency surgery and antibiotic therapy. Participating in the programs and in the panel discussions will be Professor George W. Pickering of London, Professor Herbert John Seddon of Oxford, England, and Sir Howard Florey of Oxford, noted for his clinical research on penicillin.

The centennial committee also announces that the Philadelphia Festival Orchestra, made up entirely of members of the world famous Philadelphia Orchestra, will provide music for the opening general meeting on Tuesday night, June 10, under the leadership of concertmaster and associate conductor Alexander Hilsberg. Mr. Hilsberg was recently appointed head of the orchestra department of the Curtis Institute in Philadelphia.

The Board of Trustees announces a dinner to be given to the presidents and other officers of organizations associated with medicine, distinguished publishers, industrialists and statesmen. This dinner will be held Saturday evening, June 7, in Atlantic City. The speakers on this occasion will be General Omar Bradley of the Veterans Administration; Mr. Basil O'Connor, chairman of the American Red Cross and president of the National Foundation for Infantile Paralysis, and Mr. H. W. Prentis Jr., president of the Armstrong Cork Company.

Additional announcements relative to various features of the annual session will be made weekly under the heading of Association News in The Journal. The preliminary program and complete information relative to various other features of the annual session will be published in The Journal for May 3.

OXALIC ACID

Oxalic acid, one of the earliest known organic acids, was prepared in crystalline form by Scheele in 1785. The toxicity of this compound has long been recognized and the adverse effects of its administration are attributed to its chief chemical reaction, namely the formation of a highly insoluble precipitate with calcium. However, many of the common articles of our diet contain oxalates[1] and, conversely, on experimental rations extremely poor in preformed oxalate, this substance continues to be present in the blood and urine. Oxalic acid, it has been claimed,[2] is a product of intermediary metabolism, particularly of carbohydrate.

The conviction that oxalate in food exerts a deleterious influence on the utilization of calcium was enhanced by the observation of Finke and Sherman[3] that experimental animals retained far less calcium when a portion of the dietary calcium was provided by spinach than when included as kale. The oxalate content of spinach and the lack of oxalate in kale were associated with the difference in utilization of the calcium of the diets. Other studies[4] of similar nature confirmed this general thesis. However, still other observations have failed to support the foregoing view; with diets adequate in vitamin D, calcium and phosphorus, as much as 0.9 per cent oxalate did not adversely affect growth and skeletal development in rats.[5] Again, in a study on young children, it was shown that neither spinach nor oxalate in modest amounts interfered with the utilization of calcium.[6]

Gortner and his co-workers[7] contributed to the physiologic chemistry of oxalic acid in another direction. These workers had previously demonstrated that the enamel of the teeth of rats is etched by solutions of sulfuric, citric, lactic and phosphoric acids with a p_H of 2.6. Oxalic acid of similar p_H not only did not have this effect but also protected the enamel against the other acids. Examination of the teeth after giving oxalic acid or sodium oxalate showed that there was present on the surface of the enamel a calculus-like encrustation which apparently exerted a protective action against erosion by the other acids. These observations recall the observation[8] that the oxalate ion reduces the solubility of powdered dental enamel in solution with an acid reaction.

The need for new investigations of the physiologic chemistry of oxalic acid is apparent from the foregoing account of current conflicting views. The clinician is deeply interested, for the precipitation of calcium oxalate in the renal tubules, ureters and urinary bladder is said to account for some 40 per cent of the cases of urolithiasis. Furthermore, with the recognition that the dicarboxylic acids take part in the metabolism of all the major foodstuffs, the biologic significance of oxalic acid requires more clearcut definition.

WHAT IS "NORMAL"?

What is the meaning of the term "normal" as applied to the human body? The results of physical examinations and laboratory tests are often recorded with the word "normal" jotted down with an easy assumption of accuracy entirely unjustified by the facts. In a discussion of this subject Ryle[1] says that "normal" is commonly considered as synonymous with "healthy"; but that label too needs better definition.

Probably most physicians simply mean by "normal" that an obviously demonstrable pathologic lesion has not been found. Yet, as Ryle points out, even this is questionable. Palpable epitrochlear glands, for example, which may be as large as a cherry stone, are demonstrable in about 40 per cent of adult men, unrelated to the presence of syphilis or other generalized disease of the lymph nodes. To say that the presence of palpable epitrochlear glands, therefore, is or is not normal raises an interesting question. A similar variability, Ryle says, obtains in respect to practically all measurable features of anatomy and physiologic activity. Organs and structures have a range of variation in size, shape or position. With the introduction of chest radiography, the diagnosis of "hilar tuberculosis" based on misinterpretation of the normal root shadows was once fashionable. Expensive abdominal supports and unsound surgical procedures which formerly were commonly employed led, after the introduction of the barium meal, to the frequent diagnosis of dropped stomach or dropped bowel. Variation in the human body is inherent in the race.

Where bodily function is concerned a sharp demarcation between inborn variations of health and induced variations of disease is not possible. Furthermore, a structure or function showing an extreme degree of variation from the mean may contribute to certain predispositions to disease or injury. The tall man, Ryle says, is more likely to hurt his head passing through a doorway. Some one with a native hyperchlorhydria and rapidly emptying stomach may be more likely to develop or retain a duodenal ulcer than some one with a less active organ and low gastric acidity. A complete standardization of structure and function would be incompatible with life. Variability of one individual from another and variability influenced by age, sex and activity in the population or species are essential to survival.

The chief difficulties in clinical medicine are encountered at the extreme ranges of natural variation. When does the pulse rate cease to be "normal"? At what point do the heart sounds, the strength of the knee jerk, the size and characteristics of the tonsils or the state of the thyroid pass from "normality" to the stage of disease? These are fundamental questions complicated in practice by the fact that the clinician is preoccupied with the sick and lacks access to and possibly interest in healthy controls. This largely one-sided view should not be overlooked by the practicing physician if his concept of normality is to imply, as it should, merely that the structure or function examined lies within a "range" not apparently reflecting any disease process.

Some variation, as Ryle says, can be measured and more accurate definitions given of the "healthy range." The pulse rate, the body temperature, the hemoglobin and the basal metabolic rate are examples belonging to this group. For each of these, however, constant reevaluation is necessary. There is no sharp dividing line between health and disease. The dictionary definition of "normal" does not therefore mean the same as the term does when employed by physicians in reference to the human body.

Current Comment

MEDICAL SERVICE AREAS

Elsewhere in this issue appears an article prepared by the Bureau of Medical Economic Research which describes a new approach to the study of the supply of medical service in the United States. The heretofore accepted measure of supply has been the number of physicians per county. This number is used to express a ratio of the number of people per physician. The method of measurement now being developed by the Bureau is derived from those retail marketing area principles which are applicable to the study of medical service areas. Such service areas would be far more realistic, for they would be based on a conception of medical service which is not confined within political borders. A physician does not limit his practice to those patients who reside within the county in which his office is located. His service may reach beyond the county. The geographic area in which the physician actually conducts his practice is the medical service area which must be used in any realistic study of the supply of medical care. The development of medical service areas for the entire country is an important step in the creation of a true economic picture of the effective distribution of physicians.

EDWARD L. BORTZ SUCCEEDS TO PRESIDENCY

As announced in the Organization Section in this issue, Dr. Olin West, who was chosen President-Elect of the American Medical Association in 1946, has resigned the office because of ill health. According to the Constitution and By-Laws of the Association, Dr. Edward L. Bortz, Philadelphia, elected Vice President in 1946, succeeds to the office of President-Elect and will be inaugurated as President at the annual session of the Association to be held in Atlantic City, June 9-13. Dr. Bortz was born in Greensburg, Pa., Feb. 10, 1896. He received the A.B. degree from Harvard in 1920 and the degree of M.D. in 1923. Following his internship at the Lankenau Hospital from 1923 to 1925, he studied abroad at the University of Vienna and the University of Berlin during 1925-1926 and gave further special attention to pathology at the Mayo Clinic and the University of Illinois Medical School. He then became instructor in the Department of Pathology at the University of Pennsylvania School of Medicine and the Graduate School of Medicine from 1930 to 1932. He has been associate professor of medicine at the Graduate School of Medicine at the University of Pennsylvania since that time and also chief of Medical Service B at Lankenau Hospital. He has been a director of the Philadelphia County Medical Society and chairman of its committee on public relations and was president in 1940. He has also been chairman of the Committee on Scientific Business of the College of Physicians of Philadelphia and chairman of the Committee for the Study of Pneumonia Control of the Pennsylvania State Medical Society. Dr. Bortz has been a Fellow of the American College of Physicians since 1929 and received the certificate of the American Board of Internal Medicine in 1937. He has been assistant editor of the Cyclopedia of Medicine since 1929. In 1939 he received the Meritorious Service Medal for distinguished service to the commonwealth of Pennsylvania, the award being made by former Pennsylvania Governor George H. Earle. In 1943 he was presented with the Founders Medal of the Association of Military Surgeons for exceptional services rendered in connection with the arrangements for its assembly in Philadelphia. During World War II he was on active duty as lieutenant commander and later promoted to captain in the United States Navy, serving from January 1942 through January 1944. He was made a member of the Council on Scientific Assembly of the American Medical Association in 1942 and became its chairman in 1945. He is also chairman of the Committee on National Emergency Medical Service of the American Medical Association. He was a member of the House of Delegates in 1945. Dr. Bortz has served the Association efficiently; to him may be assigned much of the credit for the arrangement of excellent programs in the General Scientific Meetings held during his membership on the Council on Scientific Assembly.

Edward L. Bortz, M.D.

RUBELLA IN PREGNANCY

The tragic effects on the child that may follow rubella in the early months of pregnancy are now widely known. The first Australian observations have been confirmed by numerous reports. The association of rubella in pregnancy with deaf-mutism is pointedly emphasized in a recent letter by Sanderson, an English physician[1] whose granddaughter aged 6 years is a deaf-mute. Her mother had German measles in the third month of her pregnancy. An excellent little school was found for the child. In this school there were fifteen deaf-mute children, "all of the same age and all apparently victims of an epidemic of German measles" in 1940. In thirteen of these fifteen children the history revealed that the mother had German measles in the early months of pregnancy. This is, as the letter says, "strong evidence on the problem of etiology." The tragedy of deaf-mutism and of still other disasters that have come to be associated with rubella occurring in early pregnancy naturally brings up the question of inducing abortion in pregnancy complicated by rubella.

ORGANIZATION SECTION

THE ATLANTIC CITY SESSION

GENERAL SCIENTIFIC MEETINGS

Monday, June 9

Presiding Officer: Clyde L. Cummer, Cleveland

2 P. M.

The Antihistamine Drugs.	George L. Waldbott, Detroit.
The Emergency Treatment of Vascular Occlusions.	Edgar V. Allen, Rochester, Minn.
Significant Trends in Cancer Research.	Stanley P. Reimann, Philadelphia.
Cardiac Recovery.	Professor George W. Pickering, London, England.

Intermission

Presiding Officer: Henry R. Viets, Boston

3:30 P. M.

Panel: The Modern Management of Heart Disease.

Moderator: Paul D. White, Boston

Diuretics.	Arthur C. de Graff, New York.
Digitalis.	Harry Gold, New York.
Quinidine.	Louis N. Katz, Chicago.

Distinguished Guest: Professor George W. Pickering, London, England
"Hypertensive Encephalopathy."

Question and Answer Period.

5 P. M.

General Summary. Paul D. White, Boston.

Tuesday, June 10

Presiding Officer: Clyde L. Cummer, Cleveland

9 A. M.

The Obstructive Prostate.	Frank Hinman, San Francisco.
Psychosomatics: The Liaison Between Internal Medicine and Psychiatry.	Edward A. Strecker, Philadelphia.
Poliomyelitis.	Hart E. Van Riper, New York.
Nerve Grafting in the Limbs.	Professor Herbert John Seddon, Oxford, England.

Intermission

Presiding Officer: Charles H. Phifer, Chicago

10:30 A. M.

Panel: Emergency Surgery.

Moderator: R. Arnold Griswold, Louisville, Ky.

Head Injuries.	Barnes Woodhall, Durham, N. C.
Chest Injuries.	Brian B. Blades, Washington, D. C.
Abdominal Injuries.	Pat R. Imes, Louisville, Ky.
Extremities.	Mather Cleveland, New York.

Distinguished Guest: Professor Herbert John Seddon, Oxford, England

Question and Answer Period.

12 M.

General Summary. R. Arnold Griswold, Louisville, Ky.

Presiding Officer: L. W. Larson, Bismarck, N. D.

2 P. M.

Skin Problems of the Elderly.	Oliver S. Ormsby, Chicago.
Cancer of the Uterus.	Emil Novak, Baltimore.
Radioactive Products in Medicine.	Stafford Warren, Los Angeles.
New Antibiotic Agents.	Sir Howard Florey, Oxford, England.

Intermission

Presiding Officer: Clyde L. Cummer, Cleveland

3:30 P. M.

Panel: Antibiotic Therapy.

Moderator: Wesley W. Spink, Minneapolis

Streptomycin.	Chester S. Keefer, Boston.
Chemotherapy in Surgery.	John S. Lockwood, New York.
Development of Bacterial Resistance to Antibiotics.	Charles Phillip Miller, Chicago

Distinguished Guest: Sir Howard Florey, Oxford, England

Question and Answer Period.

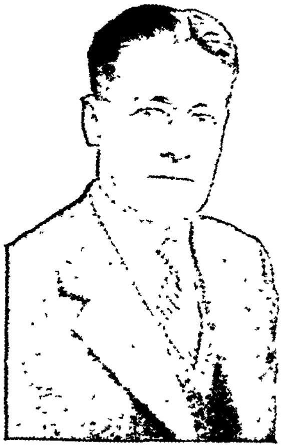
General Summary. Wesley W. Spink, Minneapolis.



Sir Howard Florey

Medical Economics

MEDICAL SERVICE AREAS IN THE UNITED STATES

FRANK G. DICKINSON, Ph.D.
Director of the Bureau of Medical Economic Research
Chicago

A study of the supply of medical service can best be made by disregarding the method now in general use, that of determining the number of people per physician in counties, townships or other political areas. An entirely new concept, based on established marketing principles, would provide a considerably more meaningful measurement and would replace what is now inadequate and misleading information on the supply of physicians in the United States.

Before explaining this new concept, one must first examine the old one, to find wherein it errs. It is customary to state the population in relation to the number of physicians as a ratio of *population to physicians within a specific area.* X County has 1 physician to 750 of population; Y County has 1 physician to 1,500 of population. These statistics are accurate, but how significant are they? Counties are political units, but medical care is an economic service that has no relation to political boundary lines. A physician is not a county coroner or a county sheriff. Many of his patients may come from areas outside the county in which his office is located. Our attention is called to the fact that approximately eighty counties do not have a resident physician. Many counties do not have a resident plumber or a resident electrician. A county is a political area, and these tradesmen—like physicians—render an economic service.

A particularly vivid case in point is demonstrated on a certain county map of the state of Minnesota, each county having been shaded according to the number of physicians per thousand of population. White counties had 1 physician to 1,000 population or less. *Black counties had 1 physician to 3,000* or more. Various other shadings were included between the two extremes. Hennepin and Ramsey counties, locale of Minneapolis and St. Paul, were, of course, white. Anoka County, which borders these two counties, was black, indicating a ratio of 1 physician to *3,000 or more people. Does this mean that the people living* in Anoka County could not obtain adequate medical care because of the small number of physicians residing in this county? It would be wrong to assume that this was the case. Actually, the population of Anoka secures its medical care, does most of its shopping and works in the centers located in the two adjacent counties not many miles distant. There is urgent need for a new map of medical service, one that will not show county lines but will be based on actual medical service areas.

To define a medical service area, we would do well to consider principles applied to the study of retail trading areas. Every store has an area or territory from which it can logically expect to secure customers. The news counter in an office building can expect to sell to people entering the building. A neigborhood grocery store may draw customers from a radius of a few blocks. A department store in the central shopping district of a large city may attract customers from a distance of many miles. A retail trade area means the territory from which the stores in a town, or a district within a city, secure or can secure a considerable part of the purchases made by the consumers. A physician renders service to people residing in a territory closely related to the retail trading area.

There are three types of retail trade areas: for fashion goods, for service goods and for convenience and bulk goods. Convenience and bulk goods are usually purchased as near the home as possible; consumers will travel farthest to obtain fashion goods. Medical care is a service good, and it is with the area in which this service is purchased that we are concerned. The question arises as to the possible necessity of differentiating between the area from which a physician draws patients to his office and the area which he services in making his home calls; furthermore, the area served by specialists differs from the area served by the general practitioner, *and these differences are worthy of* future study. In this preliminary study of the medical service area it will be sufficient to refer to a medical service area as including both office and home calls and to average out the differences roughly between "specialist" and "general practitioner" areas.

Market analysts, in discussions of retail trading areas and in attempts to mark them off on a map, usually distinguish between primary and secondary trading centers. A trading area will normally include one primary trading center and a number of secondary trading centers. For our purposes I will say that there will be a number of secondary centers in our medical service area and that these secondary trading centers will be *smaller towns having 1 or more physicians. The primary trading* center draws a considerable amount of trade from the surrounding territory and loses relatively little trade of its own large city residents to the smaller secondary trading-center towns.

It must be remembered that there are no absolutes in marketing areas. The secondary center loses a large portion of its trade to the primary center but does retain some of the trade. For certain types of goods, food, small service and convenience goods, it retains a considerable amount of the trade. The primary center, while drawing from a large area, does lose a small amount of the trade of its residents to the secondary centers. Marketing areas can never be absolutely defined. Medical service areas, following the same principles, cannot be absolutely defined. One town may draw from an extremely large area—an area which it is impossible to define on a map. A medical service map of Rochester, Minn., home of the Mayo Clinic, might conceivably include New Zealand. Such a center as Rochester might be called a "prime-primary center," but it is customary to use only the terms primary and secondary trading centers. Some primary centers have, of course, far more draw*ing power than others. Medical service areas around great* medical centers such as Rochester may receive special treatment after all the other areas have been established; they will be featured in later studies of "specialist vs. general practitioner" areas. Medical service areas drawn on state highway maps will *define the geographic area in which the majority of medical* services of all types is obtainable. Some of these areas will be better defined than others; yet even the most hastily and carelessly circumscribed areas will, I believe, provide a closer approximation of the realities of medical service than county areas.

The Bureau of Medical Economic Research has undertaken the task of setting up medical service areas for the United States. As a preliminary step, maps have been sent to all the county medical societies through the state secretaries, and the county secretaries have been asked to mark off on the map of their state the area which the physicians in their primary medical service center, if any, service. If the county has no such primary medical service center within its borders, then the county will be included in one or more medical service areas whose primary center or centers lie outside that county. Not every *county will have a primary medical service center, just as not* every county will have a primary trading center. The response of the state and county secretaries to this first project has been excellent, and the areas which show up on the state maps have slight relation to the county boundary lines. From the first studies it is estimated that medical service areas will total approximately one half of the number of counties within a state.[1]

The results so far received show much overlapping; secretaries in the nearby larger counties separated by a rural county may both claim more than one half of this rural county, thereby including portions of this rural county in both medical service areas. This overlapping is usual and customary *in the early* stages of market research studies. The state secretary should feel encouraged by this overlapping, because it shows that the county secretaries are trying to do a good job. One of the tasks of the state secretary will be to get the county secretaries involved to allocate the disputed territory so that the overlapping will be eliminated finally. Mutually exclusive areas are to be expected after consultation with the various county secretaries and after consideration of the trading habits and customs of the people in that particular area of the state.

---

[1] P. D. Converse has made a study of retail trading areas in Illinois and has defined less than forty such areas. There are 103 counties in Illinois. Reilly's Law of Retail Gravitation was the method used to mark off the areas. Retail Trade Areas in Illinois, University of Illinois, Urbana, 1946, p. 16.

At the state level there will be overlapping because people who are near the border of the state may look to the large city just across the state border for a considerable portion of their medical service. The elimination of these overlapping interstate areas will require conferences between the state secretaries concerned. These overlapping areas should be eliminated, therefore, as the last step in the process of developing mutually exclusive medical service areas.

When the medical service areas comprising every square mile of the United States have been completed, every medical service area will in normal times have one or more physicians, and no medical service area will be without the services of a physician. Further study may be required to determine the number and percentage of families in an area which are more than 30 miles or thirty minutes from a physician.

The problem of eliminating overlapping areas in some instances may require some formal statistical procedures. The allocation of a disputed area could be solved scientifically by asking all (or a good sample of) the doctors (specialists and general practitioners) within a reasonable distance from the disputed area to record for the first week in each of twelve successive months the home town of each and every patient (home, office or hospital) seen during the week. These records, when sorted by towns in the disputed area, would clearly reveal whether more patients from the disputed area used the medical service of town A or town B more frequently. In fact, this technic would be the best method to use in setting up the medical service areas in the first place, but the Bureau of Medical Economic Research recognizes that such a requirement would be extremely formidable and should be used only as a last resort.

The vital question of the supply of medical care and the distribution of physicians may be answered in the development of this new concept of medical service areas. Its primary significance will be that it will show far more accurately than previously used methods the areas in which physicians practice and the extent to which medical services are available to the people of the United States.

A complete medical service map of the United States will be only the first major step in the Bureau study of the supply of medical service.[2] It is the first step because it answers only the geographic questions of supply. The population per physician in a medical service area treats all doctors as equal units of supply; it is a quantitative and not a qualitative index of supply. The second step in the study of the supply of medical service will be functional and qualitative. It will not treat all doctors as being equal on the supply side of medical economics; it may require several years to complete.

Washington Letter

(From a Special Correspondent)

April 2, 1947.

A. M. A. Position on Health, Education and Security Department Stated

Spokesmen for the American Medical Association testified before the Senate Committee on Executive Department Expenditures that the A. M. A. "is opposed to having health activities grouped with other activities in a department with cabinet status." Dr. R. L. Sensenich of South Bend, Ind., chairman, and Dr. James R. Miller of Hartford, Conn., member of the A. M. A. Board of Trustees, testified at hearings on two bills for establishment of a Department of Health, Education and Security activities. They declared that they are in favor of the bill sponsored by Senator Taft, Republican of Ohio, to create a National Health Agency composed of the U. S. Public Health Service and several other federal health units, most of which are now under the Federal Security Agency. Mr. Taft said that if his bill for a new federal department was passed he would withdraw the conflicting National Health Agency measure. Other medical witnesses spoke in support of a bill to set up a Department of Health, Education and Security with a secretary, an undersecretary, and two assistant secretaries.

General Eisenhower Says Lack of Doctors Is Army's Chief Problem

General Eisenhower, Army Chief of Staff, said that the War Department's "worst problem" is the national shortage of doctors and the reluctance of medical practitioners to join the regular army. He informed the Senate Armed Services Committee that there is a proposal before the Budget Bureau to improve the Army Medical Service by hiring civilian consultants and raising the pay of physicians. Also considered is a plan to combine Army and Veterans Administration hospital services. General Eisenhower said that the Army must be ready to look after medical needs of an atomic war. He declared that in global warfare all medical services should be under the control of one man. The question was brought up during hearings on the Army-Navy Unification Bill when Chairman Gurney, Republican of South Dakota, suggested that a medical man serve on the Joint Chiefs of Staff to assure "adequate consideration" of the problem. General Eisenhower agreed with Senator Russell, Democrat of Georgia, that the problem goes beyond the Army and the Navy because there are not enough facilities in American medical schools to serve the nation's needs. General Eisenhower said that General Omar Bradley, Veterans Administration chief, told him that only one in ten former service men taking premedical courses can be accommodated in American medical colleges.

Dr. Thomas Parran Delivers Annual Kober Lecture

In recognition of his outstanding contribution to medical research, Dr. Thomas Parran, Surgeon-General, U. S. Public Health Service, delivered the 1947 Kober Lecture at Georgetown University. Dr. Parran spoke on "Research and Total Health." Under terms of the Kober Foundation an outstanding physician is selected each year to lecture on March 28, birthday of the late Dr. George Martin Kober, former dean of Medicine of Georgetown University. Dr. Eugene F. DuBois, professor of physiology at Cornell University Medical College, was selected by the Association of American Physicians as Kober medalist for 1947.

Capital Is Host to Nurses from Thirty-One Countries

Nurses from thirty-one countries will be guests in Washington, D. C., during the week of May 4 when the Congress of the International Council of Nurses meets here for committee meetings, inspection of medical facilities and sightseeing. The group will spend the following week at Atlantic City, N. J. The American Nurses Association, through the State Department, invited thirty-five nations to send delegates, and acceptances have been received from all but four, Bulgaria, Yugoslavia, Germany and Japan. The Soviet Union is not a member.

New Medical Clinic Founded in Washington

Dr. Wallace M. Yater, formerly with the Mayo Clinic, announced establishment here of a clinic patterned after that of the Mayo Brothers and offering diagnostic and treatment service in many phases of medical and surgical practice. Dr. Yater said that two members of his staff, Drs. Robert J. Coffey, surgeon, and Katherine Knop, child specialist, were formerly with the Mayo Clinic. It is planned to have a staff of sixteen by July, with fellowships for three young physicians.

Doctors Urged to Use "Plain English"

Clark D. Bridges, director of conservation service, Zurich Insurance Company of Chicago, told a clinic of Rehabilitation Agencies of thirteen states that "use of plain English" instead of highly technical terms in medical diagnoses would benefit not only the physically handicapped but society. He said that most job placements are made by laymen who know nothing of medical terms. If the language used could be understood, there would be a great reduction in the number of unsuccessful placements.

---

[2] An economist is always interested in both demand and supply. On the demand side, an interesting approach is described in a preliminary report of a study being made to determine the need for medical care among Michigan farm families. A sample was studied in order to judge the reliability of medical need schedules used by interviewers of selected families; the members of these families interviewed were subsequently examined by physicians in order to check the validity of the medical needs reported to the interviewers. The study is "The Determination of Unmet Need for Medical Attention Among Michigan Farm Families," by Charles R. Hoffer and Edgar A. Schuler of Michigan State College in cooperation with Dr. Rosalie Neligh and Dr. Thomas Robinson, University of Michigan Medical School.

Official Notes

RESIGNATION OF DR. OLIN WEST

The Board of Trustees of the American Medical Association regrets to announce the resignation of Dr. Olin West from the position of President-Elect. Under the Constitution and By-Laws the Board of Trustees has notified Dr. Edward L. Bortz, Vice President, that he succeeds to the office and becomes President-Elect. Following is the letter of resignation received from Dr. West:

Dr. R. L. Sensenich
Chairman, Board of Trustees
American Medical Association

My dear Doctor Sensenich:

Because of continued and possibly permanent impairment of health, I feel compelled to submit to the Board of Trustees, through you as its Chairman, my resignation as President-Elect of the American Medical Association, to take effect immediately.

I take this step with the greatest possible regret, because of having been signally honored by the action of the House of Delegates in electing me to this high office, as well as because of my devotion to the Association and to its ideals. It has been my most earnest desire and my strongest intention to do all that I could do to promote the great cause that the Association has served so well for nearly one hundred years. I sincerely hope that even as an humble member in the ranks I can make some small contribution toward the success of the very worthy aims of our great society.

I am now firmly convinced that I cannot properly perform the duties of the President-Elect and, later, those imposed on the President and that, in all fairness to the Association, my resignation should be submitted and officially accepted.

It now seems probable that I shall not be able to attend the Centennial Session to be held in Atlantic City, in which case I hope you, as Chairman of the Board of Trustees, will present my apologies for my failure in office. I hope that the House of Delegates will believe that "the spirit was willing but the flesh was weak."

I have an abiding faith in the A. M. A. and in the sincerity, integrity and soundness of judgment of those who have served and now are serving as members of its official bodies. May the richest of blessings come to all of them!

Very truly yours,
OLIN WEST.

Coming Medical Meetings

Alabama, Medical Association of the State of, Birmingham, April 14-16. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for Thoracic Surgery, St. Louis, May 28-30. Dr. Richard H. Meade Jr., 55 E. Washington St., Chicago 2, Secretary.

American Association of Industrial Physicians and Surgeons, Buffalo, N. Y., Statler Hotel, April 26-May 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, May 16-17. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland 6, Secretary.

American Association of the History of Medicine, Cleveland, May 25-26. Dr. Howard Dittrick, 2020 E. 93d St., Cleveland 6, Secretary.

American Association on Mental Deficiency, St. Paul, Minn., May 28-31. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American College of Physicians, Chicago, April 28-May 2. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Secretary.

American Laryngological Association, St. Louis, April 23-24. Dr. Arthur W. Proetz, 12 Westmoreland Place, St. Louis 8, Secretary.

American Laryngological, Rhinological and Otological Society, St. Louis, April 25-26. Dr. C. Stewart Nash, 288 Alexander St., Rochester 7, N. Y., Secretary.

American Otological Society, St. Louis, April 21-22. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

American Pediatric Society. Stockbridge, Mass., May 13-15. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Chicago, May 18-22. Dr. Maurice Visscher, University of Minnesota, Minneapolis, Secretary.

American Psychiatric Association, New York, Hotel Pennsylvania, May 19-23. Dr. Leo H. Bartemeier, General Motors Bldg., Detroit, Secretary.

American Society for Clinical Investigation, Atlantic City, Chalfonte-Haddon Hall, May 5. Dr. Eugene A. Stead Jr., Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Chicago, May 19-23. Dr. Frieda S. Robschlit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Chicago, May 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Va., Secretary.

American Society for Research in Psychosomatic Problems, Atlantic City, May 3-4. Dr. Edwin G. Zabriskie, 714 Madison Ave., New York 21, Secretary.

American Society of Biological Chemists, Chicago, May 18-22. Dr. Otto A. Bessey, Public Health Research Institute, New York 9, Secretary.

Arizona State Medical Association, Tucson, May 7-10. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 17-19. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 6-7. Dr. Joseph T. Wearn, Lakeside Hospital, Cleveland 6, Secretary.

California Medical Association, Los Angeles, Hotel Biltmore, April 30-May 3. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, New Haven, April 28-30. Dr. Creighton Barker, 258 Church St., New Haven 10, Secretary.

Federation of American Societies for Experimental Biology, Chicago, May 18-22. Dr. William H. Chambers, 1300 York Ave., New York 21, Secretary.

Florida Medical Association, Miami, April 20-23. Dr. Robert B. McIver, P. O. Box 1018, Jacksonville, Secretary.

Georgia, Medical Association of, Augusta, Bon Air Hotel, April 22-25. Dr. Edgar D. Shanks, 478 Peachtree St. N. E., Atlanta, Secretary.

Hawaii Territorial Medical Association, Lihue, Kauai, May 1-4. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu 53, Secretary.

Illinois State Medical Society, Chicago, Palmer House, May 12-14. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.

Iowa State Medical Society, Des Moines, April 16-18. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Topeka, May 12-15. Dr. John M. Porter, 512 New England Bldg., Topeka, Secretary.

Louisiana-Mississippi Ophthalmological and Otolaryngological Society, Biloxi, Miss., Buena Vista Hotel, May 5. Dr. Edley H. Jones, 1301 Washington St., Vicksburg, Miss., Secretary.

Louisiana State Medical Society, New Orleans, May 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 22-23. Dr. W. Houston Toulson, 1211 Cathedral St., Baltimore 29, Secretary.

Massachusetts Medical Society, Boston, Hotel Statler, May 20-22. Dr. Michael A. Tighe, 8 Fenway, Boston 15, Secretary.

Medical Library Association, Cleveland, Wade Park Manor, May 27-29. Miss Heath Babcock, New York State Medical Library, Albany 1, New York, Secretary.

Mississippi State Medical Association, Biloxi, May 6-8. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

Nebraska State Medical Association, Omaha, April 28-May 1. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New England Diabetes Association, Boston, City Hospital, April 16. Dr. James H. Townsend, 330 Mt. Auburn St., Cambridge, Mass., Secretary.

New Jersey, Medical Society of, Atlantic City, Haddon Hall, April 22-24. Dr. Alfred Stahl, 160 Lincoln Ave., Newark 4, Secretary.

New Mexico Medical Society, Albuquerque, April 30-May 3. Dr. H. L. January, 221 West Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, May 5-9. Dr. Walter P. Anderton, 292 Madison Avenue, New York 19, Secretary.

North Carolina, Medical Society of the State of, Virginia Beach, Va., Cavalier Hotel, May 12-14. Dr. Roscoe D. McMillan, P. O. Box 232, Red Springs, Secretary.

North Dakota State Medical Association, Fargo, May 25-27. Dr. L. W. Larson, 221 Fifth St., Bismarck, Secretary.

Northern Tri-State Medical Association, Detroit, April 8. Dr. John L. Stifel, 232 Michigan St., Toledo 2, Ohio, Secretary.

Ohio State Medical Association, Cleveland, May 6-8. Mr. Charles S. Nelson, 79 E. State St., Columbus 15, Executive Secretary.

Oklahoma State Medical Association, Tulsa, Mayo Hotel, May 14-16. Mr. R. H. Graham, 210 Plaza Court Bldg., Oklahoma City, Executive Secretary.

Rhode Island Medical Society, Providence, May 14-15. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.

Society of American Bacteriologists, Philadelphia, May 13-16. Dr. Leland W. Parr, 1335 H St. N. W., Washington 5, D. C., Secretary.

Tennessee State Medical Association, Memphis, April 8-10. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.

Texas, State Medical Association of, Dallas, Adolphus Hotel, May 5-8. Dr. Holman Taylor, 1404 W. El Paso St., Fort Worth 3, Secretary.

United States-Mexico Border Public Health Association, San Diego, California, and Tijuana, Mexico, May 6-8. Dr. James A. Grider Jr., 151 U. S. Court House, El Paso, Texas, Secretary.

West Virginia Medical Association, Charleston, May 12-14. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Secretary.

Medical Legislation

STATE LEGISLATION

Arizona

Bill Passed.—H. 163, which passed the house March 13, proposes to require each applicant for a **marriage license** to present a certificate signed by a duly licensed physician stating that the applicant is free from syphilis and other venereal diseases, tuberculosis and any other chronic or malignant infectious disease.

Colorado

Bills Introduced.—H. 262 proposes the enactment of **an occupational tax on certain professions** but specifically exempts from the operation of such tax the services of chiropractors, osteopaths, physicians, surgeons, dentists, embalmers, nurses, optometrists, undertakers, chiropodists, hospitals, cemeteries or state licensed veterinarians S 361 proposes to authorize the state board of medical examiners to grant licenses to practice naturopathy defined as "the art and science of applied healing forces by the use of Physiotherapy, Hydrotherapy, Mechanotherapy, Manipulative therapy, Electrotherapy, Phytotherapy, use of Nutritions, Diets, Hygiene and Sanitary Measures and minor surgery as taught in Naturopathic Colleges Provided, however, that the use of Narcotics, poisonous herbs, poisonous drugs, serums and vaccines shall not be construed as Naturopathy as heretofore defined"

Idaho

Bill Enacted—S 102, which has become chapter 220 of the Laws of 1947, is a state **hospital survey and construction act** requiring a statewide survey of hospital facilities and the preparation of a program for the construction of additional needed facilities The act requires the appointment of an advisory hospital council and authorizes the commissioner of the state department of public health to apply for and accept federal funds to assist the state in survey and construction activities.

Illinois

Bill Introduced.—H. 283 proposes a law for the licensing and **regulation of public and private hospitals** and sanatoriums, maternity hospitals, lying-in homes, rest homes, nursing homes, boarding homes and other institutions and places providing hospitalization or inpatient or nursing care.

Indiana

Bills Enacted.—H. 450, which has become chapter 172 of the Laws of 1947, provides for the licensing, inspection and regulation of **nursing homes.** S. 50, which has become chapter 235 of the Laws of 1947, creates an Indiana **Council for Mental Health** to, among other things, prescribe by rule or regulation classification of state psychiatric personnel and to prescribe the minimum qualifications for employment in each classification.

Kansas

Bill Introduced.—H. 399 proposes the enactment of a **hospital survey and construction act** requiring a survey of existing hospital facilities and the preparation of a program for the construction of additional needed facilities. The proposal also provides for the appointment of an advisory hospital council and authorizes the application for and receipt of federal funds to assist in the survey and construction activities within the state

Maine

Bill Introduced—S 449 proposes to authorize the governor to appoint **an advisory hospital council** to advise and consult with the department of health and welfare in carrying out the administration of the existing hospital survey act.

Maryland

Bills Introduced—H 663, to amend the hospital law, proposes to designate **the state board of health** as the sole agency to represent the state of Maryland in obtaining benefits under the federal hospital survey and construction act and proposes also to authorize the governor to appoint an advisory council on hospital construction S. 358, to amend the medical practice act, proposes to exempt therefrom **Christian science practitioners** duly registered in the *Christian Science Journal* of the Christian Science Publishing Society, Boston

New Jersey

Bill Introduced.—S. 208 proposes to authorize the state department of health to purchase and distribute free, in accordance with rules of said department, **antibiotics** for use in preventing or treating communicable diseases

New Mexico

Bill Passed.—H. 45, which passed the house March 13, proposes to require all applicants for a **marriage license** to present a certificate from a physician and surgeon duly licensed to practice medicine and surgery in the state of New Mexico showing that such applicant is not, in the opinion of the physician, infected with syphilis in such a stage that it may become communicable to the marriage partner.

Bills Enacted.—S. 12, which was approved March 21, is a state **hospital survey and construction act** requiring a survey of existing hospitals and the preparation of a program for the construction of additional facilities. The act requires compliance with the requirements of the federal hospital survey and construction act and regulations thereunder S. 80, which was approved March 18, to amend the law relating to **osteopathic physicians,** provides that if the presence of an osteopathic physician on the staff of any tax supported hospital will under federal law or regulation prevent such hospital from receiving any federal funds the governing authority of such hospital will have the power to remove all osteopathic physicians from the staff of such hospital. S. 138, which was approved March 20, is an enabling act for the formation and regulation of **physicians' service plans.** S. 246, which was approved March 18, to amend **the workmen's compensation act,** authorizes an employer or insurer to be entitled to have a physical examination of any claimant by a physician of his own choice, subject to the furnishing of reports, subject to the requirement that the physician be qualified to practice medicine under the laws of this state or the state wherein the claimant resides and subject to certain other requirements, S 247, which was approved March 19, to amend the law relating to the **director of public health,** provides that such director shall be a person having a degree of Doctor of Medicine, licensed or eligible for licensure in the state of New Mexico, and fixes the director's salary at not to exceed $6,000 per year

New York

Bill Enacted.—S 167, which was approved March 8, amends the law relating to the **practice of midwifery** by requiring as a condition to annual renewal of a license evidence that the applicant has attended and conducted one or more deliveries during the twelve months last past.

North Carolina

Bills Introduced.—H. R. 703 proposes the appointment of a commission for the special purpose of studying and investigating the administration of the **various examining boards** in the state. H. 630 proposes the creation and establishment of a two year medical school at the North Carolina College at Durham

North Dakota

Bills Enacted.—H. 23, which was approved March 14, 1947, provides for the licensing of **maternity homes** for unmarried mothers and requires that every birth occurring in such a home shall be attended by a legally qualified physician, if available, otherwise by a registered nurse until the services of a legally qualified physician can be obtained. H. 33, which was approved March 15, requires **drivers of school busses** to be examined annually by a reputable physician and to present to the school board a certificate of physical fitness showing good physical and mental health, able bodied and freedom from communicable diseases, as well as normal use of both hands, both feet, both ears and both eyes. H. 127, which was approved March 15, provides for licensing of **chiropractic hospitals** by the state board of chiropractic examiners

Ohio

Bill Introduced—H. 295 proposes to authorize the use in court of evidence of the amount of **alcohol in a person's blood** taken within two hours of the time after he is arrested as shown by a chemical analysis of his blood, urine, breath or saliva. This proposal would apply to the trial of any action or proceeding arising out of acts alleged to have been committed by any person arrested for operating a motor vehicle or motorcycle while in an intoxicated condition.

Oklahoma

Bill Introduced.—H. 278 proposes to make it a misdemeanor for any person **to use the word "Doctor"** or to hold himself out as qualified to engage in the practice of any of the healing arts without holding an unrevoked license or certificate issued by the laws of the state authorizing the person to practice the healing art covered by the license.

Bills Enacted.—H. 51, which was approved March 17, amends **the chiropractic act** by requiring, as a condition for annual renewal of a license, that the applicant present satisfactory evidence that he has attended a two day educational postgraduate program during the prior year or that he was unavoidably prevented by sickness or otherwise from attending such program. H. 159, which was approved March 13, requires various practitioners of the healing art **to list descriptive letters** after their names in order to designate the branch of practice in which they engage

Oregon

Bills Enacted.—H. 7, which was approved March 12, requires all physicians licensed by the state board of medical examiners to report immediately to the local health officer the name, sex, date of birth and address of every person diagnosed as a case of **epilepsy or similar disorder** characterized by momentary or prolonged lapses of consciousness or control which is or may become chronic H. 182, which was approved March 12, to amend the chiropractic law, increases from $5 to $10 the annual **registration fee of chiropractors** and requires that at the time of applying for such annual registration the applicant must show that he has attended a three day educational program provided annually by the Oregon Association of Chiropractic Physicians S. 189, which was approved March 10, increases the **annual registration fee** of physicians from $5 to $10

Washington

Bills Enacted—H 297, which was approved March 19, 1947, requires a survey for the discovery, treatment, hospitalization, education and training of persons afflicted with **cerebral palsy** and the appointment of a committee to make such survey. H. 378, which has become chapter 168 of the Laws of 1947, requires **applicants for a license** to practice medicine and surgery to have graduated from a medical school accredited and approved by the Association of American Medical Colleges and the Council of Medical Education and Hospitals of the American Medical Association.

GOVERNMENT SERVICES

ARMY

THE AIR SURGEON PROMOTED

Malcolm C. Grow, the Air Surgeon, U. S. Army, was recently promoted to major general. General Grow graduated from Jefferson Medical College, Philadelphia, in 1909 and served with the U. S. Army in France in World War I and with the Army of Occupation in Germany. He attended the Army School of Aviation Medicine in 1928 and later was assigned to Wright Field for experimental work on winter flight clothing. He was appointed chief, Medical Division, Office of the Chief of the Air Corps, in 1935 and later surgeon, Third Air Force; Surgeon, 8th Air Force; Surgeon, U. S. Strategic Air Forces in Europe; Surgeon, Strategic and Tactical Air Forces, Guam; acting Air Surgeon, and in January 1946 became the Air Surgeon. General Grow received the John Jeffries Award of the Institute of the Aeronautical Sciences in January 1947 for outstanding contributions to the advancement of aeronautics through medical research.

LIBRARY CONSULTANTS INCORPORATE

The Association of Honorary Consultants to the Army Medical Library has been incorporated under the laws of the District of Columbia and will continue as an advisory body to the Surgeon General in matters pertaining to the library. The association is an outgrowth of an advisory board of prominent physicians and librarians appointed in 1931. The Surgeon General in 1943 appointed additional consultants, and the number has grown until there are now more than eighty-five members. The association is financed by the Rockefeller Foundation under the auspices of the American Library Association.

CONFERENCE OF LABORATORY SPECIALISTS

Field medical laboratory service was the subject of a recent conference at the Surgeon General's Office, of specialists, all of whom had been on active duty during the recent war. The meeting was called to discuss present laboratory organization in the light of recent war experience with a view toward improving its form and equipment. The chairman of the conference was Dr. Ralph Muckenfuss, New York, who commanded the First General Laboratory in Europe. In addition to the civilian specialists, medical department officers were ordered from near and distant points to attend the conference. Among the speakers were the present chief, Laboratories Branch, Surgeon General's Office, Lieut. Col. Robert L. Cavenaugh, M. C., who surveyed the laboratory service in World War II; Col. Henry C. Dooling, M. C., chief, Medical Consultant's Division, Surgeon General's Office, discussed hospital laboratory functions, stressing clinicolaboratory cooperation; Lieut. Col. Carl T. Dubuy, M. C., chief, Troop Units Division, discussed proposed changes in various medical units and tables of organization.

CELEBRATED CHINESE PUBLICATION

The Army Medical Library has acquired a copy of the Chinese Golden Mirror of Medicine (Yu Tsuan I Tsing Chin Chien), the original of which was published in 1749. The set contains an introductory volume and ninety volumes of text, with numerous woodcut illustrations. It was written in two sections by a staff of eighty persons in compliance with an imperial order, the first on internal medicine consisting of seventy-four volumes, the second on general surgery consisting of sixteen volumes. The first twenty-five volumes contain corrections of the ancient classics of Chang Chung-Ching, the "sage" of medicine, whose Essay on Typhoid was published in 216 A. D. The other volumes cover general diseases, women's diseases, children's diseases, smallpox, surgery, diseases of the eyes, method of acupuncture, bone setting and orthopedics. Special chapters consider parasitology, leprosy and inoculation, which is known to have been practiced in China since the Sung dynasty, during the reign of Emperor Teu Tsung, 1023-1063 A. D.

CONFERENCE OF ARMY CHIEF NURSES

A four day conference of chief nurses of army general hospitals in various parts of the country was held in the Office of the Surgeon General, March 18-21, to discuss problems of the postwar organization and nursing service. Major Gen. Norman T. Kirk, the Surgeon General of the Army, gave the welcoming address. Col. F. A. Blanchfield, chief, Nursing Consultants Division, stated the aims of the conference. Among the subjects discussed were the army hospitalization program, personnel in army hospitals, personnel analysis and resources, board proceedings in connection with disposition, retirement and physical standards of army nurses, the hospital supply program, the reserve program, standardization of nursing procedures, dietetic problems, physical therapy problems and efficiency ratings. A reception and dinner was held at the Officers' Club, Fort Myer, March 19, in honor of Colonel Blanchfield, whose tour of duty expires May 31.

FLIGHT NURSES

Eleven officers of the Army Nurse Corps graduated from the Army School of Aviation Medicine, Randolph Field, Texas, on March 7, as "flight nurses" after an intensive nine weeks' training course.

The first five weeks are devoted to basic military medical and surgical subjects. Nursing care and management of wounded during flight are given special consideration. Actual air evacuation flights in the continental United States provide the final four weeks of on the job training. On the completion of the course, the graduate is authorized to wear the distinctive wings of the Army Air Force flight nurse.

Col. Harry G. Armstrong, Medical Corps, commandant of the school, presented the diplomas.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Larry B. McAfee

The Legion of Merit has been awarded to Brig. Gen. Larry B. McAfee, M. C., U. S. Army (Retired), now of Denver, who was cited for his service from July 1943 to October 1945 as commanding general of Bruns General Hospital, Santa Fe, N. M. He was instrumental in accomplishing a notable expansion of the hospital, and through his exceptional knowledge of army medical methods he incorporated many improvements in its greatly increased functions. Through his professional ability and sound judgment, General McAfee effected the development of the hospital into one of the Army's finest tuberculosis institutions. Dr. McAfee graduated from George Washington University, Washington, D. C., in 1906 and entered the military service in 1908.

Colonel George E. Leone

The Legion of Merit has been awarded to Col. George E. Leone, M. C., U. S. Army, for performing exceptionally meritorious service as chief surgeon and chief air surgeon, Headquarters, United States Army Forces, South Atlantic, from July 1942 to September 1945. In discharging his responsibility for the health of troops within the area of his jurisdiction he early established a program of preventive medicine as a result of which the health of the command and of many transient personnel was maintained at a high level. He also maintained close liaison with the Brazilian army medical service and Brazilian public health officials, thereby contributing greatly to smooth relations with that country. The inauguration of a program of air evacuation of the sick and injured of the Brazilian army was greatly furthered by his persistent efforts. By his tact, professional ability and unremitting attention to duty Colonel Leone assured the smooth operation of the medical program throughout the South Atlantic area. Dr. Leone graduated from the University of Buffalo School of Medicine in 1929 and entered the military service July 1, 1929.

Colonel Tom F. Whayne

The America Typhus Commission Medal has been awarded to Col. Tom F. Whayne, M. C., U. S. Army, for rendering exceptionally meritorious service in connection with the work of the United States of America Typhus Commission during several important periods from Aug. 1, 1942 to March 8, 1946. In 1942 he assisted in the formulation of plans for the establishment of the commission. In 1943, as assistant military attaché at the American embassy in London he helped to develop the mutually beneficial American and British collaboration in world-wide typhus control. During 1944, and until he relinquished his post as chief of preventive medicine service of the United States Theater Service Forces in the European theater, he cooperated with the commission in planning and operating typhus control measures for troops and for the refugees and displaced persons coming under American jurisdiction in Europe. Professionally, administratively and as a distinguished liaison officer, Colonel Whayne aided the advancement and application of modern typhus control, contributing to the safeguarding of the health of troops and of populations. Dr. Whayne graduated from Washington University School of Medicine in 1931 and entered military service Dec. 5, 1934.

Colonel Louis F. Verdel

The Legion of Merit has been awarded to Col. Louis F. Verdel, M. C., A. U. S., of Northport, Long Island, and formerly of Roanoke, Va. The citation stated that he performed exceptionally meritorious service as manager of the Veterans Administration Hospital at Northport, Long Island, from June 1944 to February 1946. By outstanding leadership, ingenuity, professional skill, tact and complete disregard for his own health under difficulties due primarily to lack of equipment and trained personnel, Colonel Verdel administered this 2,000 patient neuropsychiatric hospital in such a manner as to render the highest standard of treatment and maintain a high state of morale among the patients, winning the confidence, praise and cooperation of relatives, local institutions and the medical profession. Dr. Verdel graduated from the National University of Arts and Science, St. Louis, in 1915 and entered the military service Feb. 12, 1944.

Colonel Hugh L. Prather

The Legion of Merit has been awarded to Col. Hugh L. Prather, M. C., U. S. Army, of Memphis, Tenn., who rendered exceptionally meritorious service as executive officer, Kennedy General Hospital, and later as commanding officer, Army General Hospital, Camp Butner, North Carolina, during the period August 1942 to March 1946. His attention to details of administration and patient care, says the citation, combined with the improvements he fostered in occupational therapy and recreational projects, promoted high morale and resulted in the highly successful operation of these medical installations. Colonel Prather's work was a material factor in the smooth and efficient service rendered by these hospitals. Dr. Prather graduated from Vanderbilt University School of Medicine in 1928 and entered military service the same year.

Lieutenant Colonel William H. Pennington

The Legion of Merit has been awarded to Lieut. Col. William H. Pennington, M. C., A. U. S., of Lexington, Ky., for exceptionally meritorious conduct in the performance of outstanding services in the Mediterranean Theater of Operations from Nov. 8, 1942 to May 8, 1945. The citation makes it apparent that as assistant chief of surgical service, executive officer and finally commanding officer of the 38th Evacuation Hospital, Lieutenant Colonel Pennington rendered thirty months of service to the sick and wounded of the Mediterranean theater on a level of superiority difficult to equal. During the Algerian, Tunisian and Sicilian campaigns, when hospitalization facilities were extremely limited, he was instrumental in the saving of countless lives. From the beaches of Paestum, across the Volturno, at Anzio, north of Rome, and at the Gothic Line he served as executive officer of the 38th Evacuation Hospital. In this position he assisted in the supervision of the professional and administrative services of this unit, and largely through his untiring and cheerful diligence combined with great technical skill, its record was one of exceptional medical achievement. As commanding officer during the final and victorious Fifth Army April offensive the spirit of cooperation which he drew from the personnel under his leadership enabled the 38th Evacuation Hospital to move three times and each time tear down, move, set up and receive patients all in one day's time. His performance was consistently exemplary and brought the highest credit both to himself and to the Medical Corps of the Army of the United States. Dr. Pennington graduated from the University of Louisville School of Medicine in 1928 and entered the military service April 15, 1942.

Lieutenant Colonel David M. Greeley

The United States of America Typhus Commission Medal has been awarded to Lieut. Col. David M. Greeley, M. C., A. U. S., of New York, who rendered exceptionally meritorious service as executive officer, Field Headquarters, United States, of America Typhus Commission, in England, France and Germany from October 1944 to March 1946. The citation explains that he was skilled and experienced in the professional and administrative aspects of investigating and controlling epidemic typhus and served with distinction not only the commission but also the chief military and civilian agencies concerned with typhus control. Colonel Greeley's activities on an international scale greatly strengthened typhus control throughout western Europe. Dr. Greeley graduated from Harvard Medical School in 1937 and entered military service Aug. 31, 1942.

Lieutenant Colonel Charles L. von Pohle

The Legion of Merit has been awarded to Lieut. Col. Charles L. von Pohle, M. C., A. U. S., of Chandler, Ariz., for performing meritorious services for the Division of Health and Sanitation, the Institute of Inter-American Affairs, from December 1942 to April 1946 as medical officer and associate chief of a field party in Bolivia, South America, and as chief of field party in the republic of Colombia, South America. Colonel von Pohle was credited in the citation for contributing to the war effort through his effective direction of the cooperative health and sanitation programs in Bolivia and Colombia, which programs aided the military operations in the production of strategic material and in the prevention of the development of conditions that would have impaired the war effort of the United States. His enthusiasm, vision and good judgment were responsible for the successful programs conducted. Dr. von Pohle graduated from the College of Medical Evangelists, Los Angeles, in 1932 and entered the military service in November 1942.

Lieutenant Colonel Arnold Eisendorfer

The Army Commendation Ribbon was recently awarded to Lieut. Col. Arnold Eisendorfer, M. C., A. U. S., of New York. The citation called attention to his "meritorious service and devotion to duty as neuropsychiatrist and chief neuropsychiatrist, headquarters, ASFTC, Fort Lewis, Washington, from July 1, 1944 to Jan. 11, 1946. His skilful handling, through utilization of outstanding professional ability, of large numbers of psychoneurotic soldiers resulted in the readjustment and return to duty of a high percentage of all persons processed, contributing materially to the welfare and record of the command."

Dr. Eisendorfer was also awarded the Oak Leaf Cluster with the citation "for meritorious service as chief, consultation service and chief neuropsychiatrist, Camp Abbot, Oregon, from May 15 1943 to June 4, 1944. At a time when the consultation se was an innovation and its development in many respects novel and untried, Major Eisendorfer, through his outstanding professional ability, leadership, ingenuity and untiring energy, organized and operated the neuropsychiatric consultation service and mental hygiene program so successfully that it became a model for other services and contributed materially to the effective utilization of manpower in the army."

Lieutenant Colonel Eisendorfer graduated from the University of Colorado School of Medicine, Denver, in 1928 and entered the service Oct. 21, 1942.

Major John W. Eschenbrenner

The Legion of Merit has been awarded to Major John W. Eschenbrenner, M. C., A. U. S., of Fort Worth, Texas, who was a member of the Air Surgeon's Board in Otorhinolaryngology. The citation stated that during the period from May 1944 to October 1945, Major Eschenbrenner performed an outstanding service in connection with the preparation of plans and studies for implementing the Army Air Forces Aero-Otitis Control Program. His personal direction of the irradiation program in the Eighth Air Force reflects great credit on himself and on the military service. Dr. Eschenbrenner graduated from Washington University Medical School, St. Louis, in 1929 and entered military service Feb. 4, 1943.

Captain Carlo Henze

The Legion of Merit has been awarded to Capt. Carlo Henze, M. C., A. U. S., of New York. He rendered exceptionally meritorious service as a medical intelligence officer engaged in the collection of information concerning German research programs of major concern to the Allied forces during the period December 1944 to April 1945. The citation mentions his imagination, skill and ingenuity, which made possible the successful completion of an investigation which brought to light the complete information regarding these German projects and their possible relationship to comparable Japanese programs. Captain Henze's accomplishments in this field were a major contribution to the medical intelligence of the Allied forces. Dr. Henze graduated from the University of Innsbruck School of Medicine, Austria, in 1933 and entered the military service Jan. 20, 1941.

Captain Amos R. Little

The Air Medal, the Legion of Merit and the Army Commendation Ribbon were recently awarded to Capt. Amos R. Little Jr., M. C., A. U. S., of Helena, Mont. The citations read in part as follows: "For meritorious achievement in aerial flight on June 15, 1944 at Crown Peak, Roosevelt National Forest, Colorado. On flying to the scene of an aircraft accident on a mountain peak at an altitude of 11,000 feet, Captain Little made a daring and exceptionally dangerous parachute jump at an altitude of only 500 feet above the peak in order to render assistance and medical care to the survivors. Despite the jagged and rocky character of the landing area, and snow and ice, he performed a highly successfully jump and was instrumental in possibly saving many lives. During the period from November 1943 to April 1946 he made a total of fifty-one parachute jumps under hazardous conditions for the purpose of rendering medical aid to the victims of accidents. His outstanding work in the field of medical research and rescue technic reflects great credit on himself and on the armed forces of the United States. Dr. Little graduated from Johns Hopkins University School of Medicine in June 1942 and entered the military service Oct. 1, 1943.

Captain Monroe J. Romansky

The Legion of Merit has been awarded to Capt. Monroe J. Romansky, M. C., A. U. S., of Washington, D. C., who rendered distinguished service in penicillin research at the Army Medical Center, Washington, D. C., from July 1942 to October 1945. The citation stated that his pertinacity in research, professional skill and devotion to duty resulted in improvements in the technics for administration of penicillin, thereby saving lives and alleviating pain and suffering. Dr. Romansky graduated from the University of Rochester School of Medicine in 1937 and entered the military service July 25, 1942.

CORRECTION

Major Harry Most.—Under Awards and Commendations in The Journal, March 22, page 874, Dr. Harry Most should have been referred to as Major instead of Captain.

VETERANS ADMINISTRATION

VETERANS ADMITTED TO HOSPITALS IN 1946

A total of 458,749 veteran-patients were admitted to Veterans Administration and non-Veterans Administration hospitals during the calendar year 1946, the Veterans Administration reports. General medical and surgical patients accounted for 83.19 per cent of the admissions, and neuropsychiatric patients for 11.77 per cent of the total. The smallest group, 4.27 per cent of the total, was the tuberculous patients. The remainder of the admissions, 3,540, were nonveteran patients including employees taken ill on the job and treated before removal to civilian hospitals, veterans of allied forces and emergency cases admitted pending removal to other hospitals. Slightly less than 50 per cent of the total number of neuropsychiatric admissions were classified as psychotic cases, the remainder being neuropsychiatric disorders other than psychosis, such as organic conditions of the nervous system, character and behavior disorders and the psychoneurotic. During the fiscal year 1946, neuropsychiatric patients discharged from hospitals had an average stay of 197 days, compared with 186 days for tuberculous patients and 34 days for general medical and surgical patients.

PARAPLEGIC CENTERS

The Veterans Administration has established seven paraplegic centers in hospitals strategically located from coast to coast. These centers, especially designed to treat veterans with spinal cord injuries, are in operation in Veterans Administration hospitals at Framingham, Mass.; Memphis, Tenn.; Van Nuys, Calif.; Staten Island, N. Y.; Richmond, Va.; Bronx, N. Y., and Hines, Chicago.

Because of a general shortage of doctors, physical therapists and others qualified to treat paraplegic patients, Veterans Administration personnel skilled in this field have been assembled at the seven centrally located hospitals. Today, because of modern medical science and developments in the field of physical medicine, many persons with paraplegia are able to lead active, productive lives. To treat each case properly, the services are needed of a medical team consisting of a neurologist, neurosurgeon, psychiatrist, urologist, plastic surgeon, orthopedic surgeon, physical therapist, occupational therapist, corrective physical rehabilitation officer, educational retraining officer, prevocational shop supervisor, social worker and nurses. The Veterans Administration has about 1,200 veteran patients suffering from injuries to the spinal cord.

PERSONAL

Dr. L. S. Eagleburger of Stevens Point, Wis., has been appointed chief medical director of the Wausau subregional office of the Veterans Administration. Dr. Eagleburger served in the Army during the recent war, and twenty-eight months of his service was in the southwest Pacific area.

Dr. O. K. Timm, recently released from the Army after more than two years of foreign duty, has been appointed clinical director of the Veterans Administration Hospital, Danville, Ill. Dr. Timm served with the Veterans Administration prior to entering the military service. In the new position he succeeds Dr. George D. Rice, who was transferred to Tomah, Wis., as manager of a new veterans' hospital.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

State Medical Meeting at Little Rock.—The seventy-first annual session of the Arkansas Medical Society will be held in the Robinson Auditorium, Little Rock, April 17-19 under the presidency of Dr. H. King Wade, Hot Springs. At the opening general session Thursday morning Dr. T. Leon Howard, Denver, will speak on "Renal Pathology in the Making." The house of delegates will meet Thursday afternoon. At the evening public meeting Dr. Harrison H. Shoulders, Nashville, Tenn., President, American Medical Association, will discuss "Some Problems in the Economics of Medical Care." Dr. Geza de Takats, Chicago, will discuss the surgical management of hypertension Friday morning. Among others Drs. Samuel Fomon, New York, will speak on "The Rhinoplastic Operation"; Henry Packer, Memphis, Tenn., "New Drugs in the Treatment of Malaria"; Alexander Marble, Boston, "Present Day Treatment of Diabetes"; Warfield M. Firor, Baltimore, "The Surgical Aspects of Cancer." A memorial service will be held Friday morning at 11:40 in joint session with the Woman's Auxiliary to the Arkansas Medical Society for the twenty-four members of the society who have died since the last meeting.

CALIFORNIA

History of Alameda County Medical Association.—Seven physicians met in the Court House in San Leandro on Aug. 18, 1860 to "draft a constitution and by-laws for the government and regulation of the prospective association." This was the beginning of the Alameda County Medical Society, which has just published a history of the organization covering a period of some eighty-five years. The origins of the book were fostered by the late Dr. Frank R. Makinson and since his death by Dr. Milton H. Shutes of Piedmont. An interesting account of the first doctors to come to California, it shows briefly the part played by them in the development of California railroads, the handling of epidemics and the fight to raise the standards of medical practice in the community. Here are the names of speakers at numerous meetings, among whom were medical authorities of that day from far and wide. The origins and development of hospitals, the expulsion of certain members of the society in the early days for advertising in newspapers and for the preparation and dispensing of "patent" medicines are reviewed. One member of the society, Dr. George C. Pardee, was elected governor of California in 1902 by a large majority. He was "one of the most beloved citizens in the history of Oakland." In 1904 it was suggested to the society that $150 be raised among the members as a contribution to the $25,000 fund that the American Medical Association proposed to create for the family of the late Dr. Walter Reed of yellow fever fame. At a meeting in 1877 it was moved and carried "that the members of the association dispense with smoking during the time of the society's sessions." Dr. J. Horatio Bundy, a member, is said to have introduced cascara sagrada to medicine. In 1917 a compulsory health bill patterned after certain European plans was devised, but at the election in the following year it was defeated by nearly 3 to 1; in Alameda County by 58,271 to 16,546. Adding to the interest of this volume are pictures of pioneer California physicians and of houses in which they lived and carried on the practice of medicine.

CONNECTICUT

Conference of Presidents and Secretaries.—The semiannual conference of the presidents and secretaries of the eight component county associations of the Connecticut State Medical Society was held in New Haven on March 20. Thomas A. Hendricks, Chicago, secretary, Council on Medical Service, American Medical Association, addressed the meeting on "Responsibilities of the Secretary of a County Medical Society." A talk on the activities of state medical journals was given by John E. Farrel, managing editor of the *Rhode Island Medical Journal*. Dr. Cole B. Gibson, Meridan, president of the Connecticut society, presided.

State Medical Meeting.—The Connecticut State Medical Society will hold its 155th annual meeting April 28-30, under the presidency of Dr. Cole B. Gibson, Meridan. The general session will be held in the high school building at Hamden. The house of delegates will meet at the New Haven Medical Association Building, New Haven, Monday afternoon. Among the speakers for the general program will be:

Dr. Alvin L. Barach, New York, Physiologic and Antibiotic Therapy in Bronchial Asthma.
Dr. Elaine P. Ralli, New York, Management of the Complications of Diabetes.
Dr. Richard Schatzki, Boston, Lesions of the Antrum of the Stomach.
Dr. W. Jason Mixter, Boston, Present Status of Management of Ruptured Intervertebral Disk.
Dr. J. William Hinton, New York, End Results and Indications for Thoracolumbar Sympathectomy.
Dr. George A. Perera, New York, Role of Sodium Restriction in Hypertension.
Dr. Herbert C. Maier, New York, Diagnosis and Treatment of Bronchiectasis.
Dr. Richard H. Sweet, Boston, Diagnosis and Treatment of Carcinoma of the Esophagus.
Dr. Franz J. Ingelfinger, Boston, Clinical Significance of Changes in Small Intestinal Function.
Dr. Samuel A. Levine, Boston, Management of Acute Coronary Thrombosis and Its Complications.

At a symposium on the treatment of peripheral vascular diseases Tuesday afternoon Drs. A. Wilbur Duryee and Irving S. Wright, both of New York, and Dr. John Homans, Boston, and at the Wednesday afternoon symposium on psychoneurosis Drs. Jacob E. Finesinger, Boston; Benjamin V. White, Hartford, and Carl A. L. Binger, New York, will speak. Section meetings to be addressed by various out of state speakers are scheduled for Tuesday and Wednesday afternoons. The annual meeting of the Woman's Auxiliary will be held on Tuesday afternoon at the New Haven Country Club. The annual dinner is scheduled for Tuesday evening at the New Haven Lawn Club.

FLORIDA

Neurology and Psychiatry Society.—The first annual meeting of the Florida Neurology and Psychiatry Society will be held April 20 at the McAllister Hotel in Miami, preceding the annual meeting of the state medical association. The permanent organization of this group is being arranged by Drs. H. Mason Smith, Tampa, and William H. McCullagh, Jacksonville. The group will be addressed by Dr. James B. Lyerly Jacksonville, on "Surgical Relief of Pain."

Annual Meeting of State Association.—The seventy-third annual meeting of the Florida Medical Association will be held in the Municipal Auditorium, Miami, April 21-23 under the presidency of Dr. Shaler Richardson, Jacksonville. The business meeting will be Monday afternoon and Tuesday morning, with election of officers scheduled for Wednesday. Besides numerous speakers, members of the association, Dr. John H. Dunnington, director, Institute of Ophthalmology, New York, will give an address Tuesday morning on "The Eye in Thyroid Disease." The Woman's Auxiliary will meet Monday and Tuesday at the McAllister Hotel. Various sections and specialty groups will hold meetings, including among others the General Practice of Medicine Society. All persons interested in the postconvention tour to Cuba are requested to communicate with Dr. Carlos P. Lamar, 1010 Huntington Building, Miami.

Temporary Permits to Practice.—To alleviate the medical needs of communities that are either wholly without or greatly in need of a physician, temporary permits to practice medicine within the state are being granted by the Board of Medical Examiners of Florida. The signed request for such services in a certain town or community must originate with the local county medical society, whose prerogative it will be to decide whether or not temporary licentiates shall come among them. The holder of a temporary permit must appear for the next regular examination (June and November); until that time he is expected to remain in his assigned community until licensed by the board. To be eligible to apply for a temporary permit, the applicant must have a diploma from an acceptable medical college of the United States or Canada. Graduates of unacceptable medical schools must take (and receive credits for) a senior year's work in an acceptable medical school of the United States or Canada or must satisfactorily complete one year's assistant residency (following one year's internship satisfactorily completed in an approved hospital) or a residency or a fellowship in medicine, surgery or other specialty in an approved hospital. Also the Florida law requires as an additional prerequisite a certificate of proficiency from the Florida Basic Science Board. The temporary permit need not be recorded. All physicians, however, register annually with the state board of health, paying a fee of $1, and must be approved or disapproved by the state bureau of narcotics for a special narcotic stamp, which is received with the narcotic permit from the collector of internal revenue in Jacksonville or the nearest center. Necessary forms to be filled out by the applicant and by the officers of the county society and then duly notarized may be obtained from Harold D. Van Schaick, Secretary, State Board of Medical Examiners, 2736 Southwest 7th Avenue, Miami 36.

ILLINOIS

Graduate Education for Local Physicians.—The Illinois State Medical Society held a meeting in East St. Louis April 3 at which authorities in various fields of medicine brought to local physicians of the Tenth Councilor District the newer trends of their specialties. It was eighth in a series of ten such meetings to be held by the society within the last year. The ninth and tenth conferences are scheduled for Mattoon April 17 and Monmouth April 24.

Personal.—Dr. Leonard M. Schuman, Springfield, U. S. Public Health Service, has been appointed chief of the division of venereal disease control in the state department of public health. Dr. Schuman was a district health superintendent with headquarters at Woodstock from August 1941 until July 1943, when he became assistant chief of the division of local health administration, Springfield, until August 1945. He is a graduate of Western Reserve University, Cleveland, 1940.

Northwestern Affiliates with Children's Memorial Hospital.—By the affiliation of Northwestern University Medical School with the Children's Memorial Hospital, Chicago, the faculty and the hospital staff will cooperate in research and teaching related to pediatrics. Further correlation of the work of the two institutions has been arranged, with senior medical students serving part time at the hospital, and staff members of Children's Memorial using the Northwestern laboratories for research. The 252 bed hospital had 3,955 inpatients in 1946 with 1,101 additional patients served in the hospital's clinic. Seventy-one per cent of the care was given free of charge.

Chicago

Personal.—Dr. George K. Fenn, associate professor of medicine, Northwestern University Medical School, and chief of staff at St. Luke's Hospital since 1943, was elected president of the Chicago Heart Association March 4.

Research at Institute for Psychoanalysis.—At the meeting of the National Advisory Mental Health Council in Washington, D. C., in January the council approved three grants for research to be conducted at the Chicago Institute for Psychoanalysis on studies of mental health in connection with physical diseases: $5,000 for a two year study of diabetes mellitus, $4,000 for a two year study of atrophic arthritis and $5,000 for a study of ulcerative colitis.

Ninety Days for Practicing Without License.—Dr. Amante Rongetti, 2900 Van Buren Street, has been sentenced to a ninety day term in the county jail for practicing medicine without a license. Dr. Rongetti, whose medical license was revoked by the state after he had been sentenced to fourteen years on manslaughter charges in 1929, was pardoned May 20, 1942 and arrested again in June 1943. The Supreme Court has ruled that Rongetti must serve the ninety day sentence.

Symposium on the Tuberculosis Problem.—A symposium on recent developments in the tuberculosis problem in Chicago will be held at 8 p. m. April 10 at the Bismarck Hotel at a joint meeting of the Chicago Tuberculosis Society and the Tuberculosis Institute of Chicago and Cook County. Speakers for the meeting are Dr. James H. Hutton, chairman, Tuberculosis Control Committee of the Chicago Medical Society; Dr. A. W. Newitt, Chicago tuberculosis control officer; E. F. Kleinschmidt, director, Tuberculosis Institute of Chicago and Cook County, and Mr. W. P. Shahan, director, Tuberculosis Association of Illinois. Reservations for the dinner to precede the meeting must be made by April 8 through George W. Holmes, secretary, telephone Juniper 3500.

INDIANA

New Obstetric and Gynecologic Society.—An inaugural dinner meeting for the newly organized Indianapolis Obstetrical and Gynecological Society will be held April 9 at the Athletic Club, Indianapolis. Dr. Frederick H. Falls, professor and head of the department of obstetrics and gynecology, University of Illinois, Chicago, will give an illustrated discussion on ectopic pregnancy. The officers of the society, organized January 22, are Drs. Charles O. McCormick Sr., Indianapolis, president; Carl Habich, Indianapolis, vice president, and Lawson J. Clark, Indianapolis, secretary-treasurer.

Third Industrial Health Conference.—The third industrial health conference will be held at Indiana University School of Medicine, Indianapolis, April 16, under the sponsorship of the Indiana State Medical Association committee on industrial health, Indiana University School of Medicine department of public health and the Indiana State Board of Health division of industrial hygiene. The meeting is open to physicians, personnel directors or safety directors. There are no registration fees. Among the speakers will be Dr. Henry H. Kessler, Newark, N. J., member, Council on Industrial Health, American Medical Association, on "Disability Evaluation"; Dr. L. E. Hamlin, medical director, American Brake Shoe Company, Chicago, "Industrial Disease of the Chest"; Dr. Leonard F. Weber, associate professor of dermatology, University of Illinois College of Medicine, Chicago, "Industrial Dermatoses"; Lawrence T. Fairhall, Ph.D., U. S. Public Health Service, Washington, D. C., "Toxicology of Heavy Metals," and Anna M. Baetjer, D.Sc., assistant professor of physiological hygiene, Johns Hopkins University, Baltimore, "Control of Upper Respiratory Diseases."

MASSACHUSETTS

Dr. Rivers to Give the Cutter Lecture.—The Harvard School of Public Health announces that Dr. Thomas M. Rivers, director of the Hospital of the Rockefeller Institute for Medical Research, New York City, will deliver the Cutter Lecture on Preventive Medicine, April 22, 5 p. m., in amphitheater D of Harvard Medical School, Boston. His subject will be "Certain Public Health Aspects of Infectious Diseases." The lectures have been held since 1912. The medical profession, medical and public health students and others interested are cordially invited.

Physicians Art Association.—The Massachusetts Physicians Art Association has been established to stimulate interest in drawing, painting, sculpture and photography. Any member of the Massachusetts Medical Society may join the association by sending $2, the annual dues, to the treasurer, Dr. Robert W. Buck, 5 Bay State Road, Boston. An exhibition will be held in conjunction with the annual meeting of the Massachusetts Medical Society, May 20-22. Additional information may be had by writing Dr. Somers H. Sturgis, Massachusetts General Hospital, Boston 14.

MICHIGAN

Alumni Clinic Day.—One of the speakers at Wayne University Alumni Clinic May 14 will be Dr. Emery A. Rovenstine, professor of anesthesia, New York University College of Medicine, and director, division of anesthesia, Bellevue Hospital, New York, on the subject "Nerve Block Therapy." Dr. Rovenstine in 1938 was guest director of anesthesia at Oxford University, England, and in 1939 guest professor of anesthesia at the University Rosario in Argentina.

NEW JERSEY

Society News.—Dr. Herbert T. Kelly, Philadelphia, chairman, committee on nutrition, Medical Society of the State of Pennsylvania, presented a paper on "Nutritional Integration in Psychosomatic Medicine" before the Middlesex County Medical Society, Metuchen, February 19.

Annual Meeting of State Medical Society.—The 181st annual meeting of the Medical Society of New Jersey will be held in Atlantic City in Haddon Hall, April 22-24, under the presidency of Dr. Frank G. Scammel, Trenton. Among the speakers Wednesday are the following physicians:

Robert E. Gross, Boston, Congenital Atresias of the Alimentary Tract.
Joseph C. Birdsall, Philadelphia, Diagnosis and Treatment of Carcinoma of Prostate.
Abraham E. Rakoff, Philadelphia, Use and Abuse of the Endocrines in Obstetrics and Gynecology.
Franklin L. Payne, Philadelphia, Diagnosis and Management of Endometriosis.
Paul C. Swenson, Philadelphia, Roentgen Findings in Functional Disturbances of Gastrointestinal Tract.
Albert F. R. Andresen, Brooklyn, Allergy in Relation to Gastrointestinal Diseases.
Max M. Strumia, Bryn Mawr, Pa., Blood Proteins.
J. Scott Butterworth, New York City, Advances in the Diagnosis and Treatment of Heart Disease.
Oswald R. Jones, New York City, The General Practitioner and Diseases of the Chest.
Hattie E. Alexander, New York, Newer Concepts and Treatment of Hemophilus Influenzae Meningitis.
Samuel Z. Levine, New York City, Metabolism and Feeding of the Premature Infant.
F. Johnson Putney, Philadelphia, subject unannounced.

General sessions will be held Tuesday afternoon and Thursday morning. An informal dinner dance will be held Wednesday at 7:30 p. m.

NEW MEXICO

State Medical Meeting and Rocky Mountain Conference.—The 1947 annual meeting of the New Mexico Medical Society will be held April 30 to May 3 in Albuquerque, N. M., in conjunction with the fourth meeting of the Rocky Mountain Medical Conference, comprising Colorado, Montana, New Mexico, Utah and Wyoming. The annual business meeting of the New Mexico society will open at 10 o'clock April 30, Dr. Charles A. Miller, Las Cruces, N. M., president, presiding. Among the physicians addressing the conference are the following from the University of Illinois College of Medicine, Chicago:

Warren H. Cole, Treatment of Gallbladder Disease.
Henry G. Poncher, Diagnosis and Treatment of Anemia in Infants and Children.
Ford K. Hick, Management of Respiratory Emergencies.
George E. Wakerlin, Clinical Application of Recent Advances in Gastrointestinal Physiology.
Henry E. Michelson, Minneapolis, Minn., Dermatologic Diagnosis and Treatment for the General Practitioner.
Alfred W. Adson, Rochester, Minn., Diagnosis of the Scalenus Anticus Syndrome.

Other doctors of medicine addressing sessions of the conference include:

Howard C. Naffziger, San Francisco, Neurologic Diagnosis as It Especially Concerns the Internist and General Practitioner.
Wendell G. Scott, St. Louis, Use of X-Rays in Diagnosis of Lesions of Large Intestine and Rectum; Low Back Pain and the Important Part That the Interpretation of Properly Taken Roentgenograms Plays in This Problem.

Ten and fifteen minute question periods will follow the addresses. Round table luncheons will be held at the Alvarado Hotel, with informal discussions by guest speakers. There will be two on general medicine and one each on pediatrics and general surgery. The banquet Friday will be informal.

NEW YORK

Personal.—Dr. Charles M. Carpenter, associate professor of bacteriology, University of Rochester School of Medicine, has been granted two months' leave of absence to direct a commission to survey certain aspects of the venereal disease problem in the Pacific theater for the Surgeon General of the Army.

University News.—Grants for cancer control studies have been made to the following two University of Rochester professors by the National Institute of Health, of which the National Cancer Institute is a unit: Dean S. Tarbell, Ph.D., now working under a Guggenheim fellowship at Oxford University, England, and John R. Murlin, Ph.D., professor of physiology, emeritus.

New York City

Psychiatric Forum.—At a meeting of the Brooklyn State Hospital Psychiatric Forum April 10 at 8:30 p. m. in the auditorium at Brooklyn State Hospital, 681 Clarkson Avenue, Brooklyn, Dr. Lauretta Bender, New York, will speak on "Schizophrenia and Childhood."

Memorial Lecture.—Dr. F. Peyton Rous, member emeritus of the Rockefeller Institute for Medical Research, delivered the Adam M. Miller Lecture on "Cancer as an End Product" at the Polhemus Memorial Building, Brooklyn, March 20. The lecture is sponsored by the Long Island College of Medicine.

Gift to Medical Center Fund.—The New York University-Bellevue Medical Center Fund has received a $100,000 gift in honor of the centennial anniversary of the birth of the late Jacob H. Schiff. The gift was made jointly by the Mortimer and Adele Schiff Foundation, Mrs. Felix M. Warburg and Frederick M. Warburg.

Research at Columbia University.—Among grants recently received by Columbia University, Dr. Frank D. Fackenthall, acting president, announced, were $44,225 from the U. S. Public Health Service for medical research, $37,815.50 from the American Cancer Society, Inc., and $20,700 from the National Foundation for Infantile Paralysis for research in muscle spasm and atrophy.

Tuberculosis Conference.—The Tuberculosis Sanatorium Conference of Metropolitan New York held its thirty-seventh clinical session at Cornell University Medical College, February 19, Dr. William G. Childress, Valhalla, chairman, presiding. Dr. Isadore D. Bobrowitz, medical superintendent, Municipal Sanatorium, Otisville, discussed "Prognosis and Clinical Significance of Minimal Tuberculosis" and Dr. William H. Roper, director, research section, Fitzsimons General Hospital, Denver, discussed the U. S. Army Medical Department's Section for Research on Minimal Tuberculosis.

OHIO

Personal.—Dr. Charles C. Cropper, Lynchburg, will complete fifty years of practice in Highland County next month. He is a graduate of the former Louisville Medical College, Louisville, Ky., and has served as a member of the board of public affairs at Lynchburg for thirty years.

Cleveland Health Museum.—The 1946 annual report of the Cleveland Health Museum, a privately supported institution which has been serving the public for six years, shows that 36,669 persons saw exhibits in the main building and many times that number at extension and loan exhibitions. Seventeen lectures were given during the year by members of the staff to outside agencies. The museum instituted last May three minute radio health broadcasts of station WTAM.

Rat Control Program.—The City of Cleveland Division of Health carried out a rat control program in the Goodrich area last month. A sound movie and a lecture on ratproofing of residences, old and new methods of rat killing and a demonstration comprised the program. Area projects of this nature are conducted in an effort to bring fundamental health services to the public on a neighborhood basis. Following a special rubbish collection to help the cleanup of premises, a "bait station" trailer was assigned to the neighborhood for several days to distribute free rat poison.

PENNSYLVANIA

Hospital News.—The Civilian Production Administration has approved the construction of a $1,463,061 building at Philadelphia State Hospital, Philadelphia. The new three story structure will house patients who are convalescing and capable of being employed at useful occupational work at the hospital.

Bone Bank Established.—Establishment of a bone bank to provide a constant supply of bone for grafting operations was announced February 21 by Dr. Leonard F. Bush, the George F. Geisinger Memorial Hospital, Danville, Pa., in a talk before the orthopedic section of the New York Academy of Medicine. The bank, already functioning, was established after experimentation at the New York Orthopedic Dispensary and Hospital. Dr. Bush said the principal value of the bank is that it eliminates the delay in having to perform simultaneous operations to remove the bone from the bone donor and to transplant it in the patient.

Postgraduate Psychiatric Training.—The Western State Psychiatric Institute and Clinic, Pittsburgh, training and research institution of the state mental hospital system, recently sponsored a number of graduate training activities for professional personnel. Last April a conference was held to provide opportunities for consideration of topics demanding cooperative thinking and activities. Specific workshops on professional problems were held after the conference, one on psychiatric treatment attended by clinical directors and physicians from state mental hospitals. A second seminar was held for clinical psychologists. In conjunction with the School of Nursing of the University of Pittsburgh, two meetings were held for graduate nurses, one for those interested in administration and another for nursing educators, which was attended by representatives from New Jersey, Ohio and Kentucky.

Philadelphia

Annual Health Institute.—The seventeenth annual health institute of the Woman's Auxiliary to the Philadelphia County Medical Society will be held April 8 at the auditorium, Philadelphia County Medical Society, Philadelphia. Dr. Pascal F. Lucchesi, Philadelphia, will discuss "Future Plans of the Philadelphia General Hospital," of which he is medical director and superintendent. Other speakers include Dr. Francis F. Borzell, vice speaker, House of Delegates, American Medical Association; Mrs. Edna M. Kech, Harrisburg, director, division of health education, State Department of Health; Dr. M. Clay Stayer, director, bureau of tuberculosis control, State Department of Health, and Dr. Norris W. Vaux, Philadelphia, secretary of health, State of Pennsylvania.

UTAH

Surgical Meeting at Ogden.—The second annual meeting of the Ogden Surgical Society will be held May 15-17 at the Thomas D. Dee Memorial Hospital, Ogden. Among the guest speakers will be Drs. Alton Ochsner and Champ Lyons, Tulane University of Louisiana School of Medicine, New Orleans; Herbert D. Adams, Lahey Clinic, Boston; Edgar V. Allen, Mayo Clinic, Rochester, Minn.; Kenneth C. Swann, University of Oregon Medical School, Portland; Paul B. Magnuson, Northwestern University Medical School, Chicago. The annual banquet will be held Friday night.

WASHINGTON

Neurologic Society.—The Seattle Neurological Society has lately been formed with William F. Windle, Ph.D., president; Paul G. Flothow, vice president, and R. Frederick Becker, Ph.D., secretary-treasurer. Full membership is open to all practicing neurologists, neurosurgeons, neuropsychiatrists or neuropathologists in Seattle and its environs and to others interested in these fields.

New Medical-Dental Building. — Ground was broken March 5 for the medical, dental and the nursing building at the University of Washington, Seattle, by Raymond B. Allen, University president, and Dr. Lee P. Sieg, Ph.D., former president. Among the guests were Drs. Ross D. Wright, Tacoma, president of the state medical association; Clarence A. Smith, Seattle, editor of *Northwest Medicine*, and Frank H. Wanamaker, president of the King County Medical Society. Construction started immediately.

GENERAL

Influenza.—According to reports from state health officers to the U. S. Public Health Service, Washington, D. C., influenza was epidemic last month in Texas, Colorado, Kansas, Georgia, Arkansas, Indiana, South Carolina and Virginia, which states accounted for 90 per cent of the total number of cases in the nation, 7,974, for the week ended March 1.

International College of Surgeons Purchases Headquarters.—The International College of Surgeons, U. S. Chapter, has acquired 1516 Lake Shore Drive, Chicago, the former Edward Blair residence, as a permanent home. The building, a four story fireproof structure designed by McKim, Meade and White, will house the offices of the college, library and projected museum and assembly rooms of the organization.

New Society to Study Arteriosclerosis.—The increasing importance of arteriosclerosis as a cause of death and a source of physical and mental disability makes urgent the early institution of effective measures for its control. Clinicians and experimentalists interested in an intensified investigation of all phases of this disease are invited to join the new American Society for the Study of Arteriosclerosis and are urged to get in touch as soon as possible with Dr. Otakar J. Pollak, Wilmington General Hospital, Chestnut and Broom streets, Wilmington 14, Del. The constituting meeting has been called for Monday, June 9, at 9 a. m. at the Hotel Strand, Atlantic City, N. J.

Meeting of Chest Physicians.—The Maryland-District of Columbia chapter of the American College of Chest Physicians will meet April 21 preceding the semiannual meeting of the Medical and Chirurgical Faculty of the State of Maryland at the Belvedere Hotel, Baltimore. Subjects for discussion are "Sarcoidosis," "Congenital Atresia of the Esophagus," "Surgical Treatment of Pulmonic Stenosis," "Chemotherapy of Tuberculosis" and "Correlation of Various Branches of Medicine and Surgery as Related to Diseases of the Chest." Among the speakers are Drs. Cameron Haight, associate professor of surgery, University of Michigan Medical School, Ann Arbor, Mich., and John A. Kolmer, professor of medicine, Temple University School of Medicine, Philadelphia.

Special Society Elections.—The American Cancer Society elected Eric A. Johnston, president of the Motion Picture Producers and Distributors of America, Inc., chairman of its board of directors at its meeting March 7 in Chicago. Dr. Edwin P. Lehman, chief surgeon of the University of Virginia Hospital, Charlottesville, was elected president, succeeding Dr. Frank E. Adair, New York City. Elmer H. Bobst, Nutley, N. J., is serving as national chairman of the 1947 campaign opening April 1 to raise $12,000,000.——At the recent meeting of the American Academy of Pediatrics in Pittsburgh Dr. John A. Toomey, Cleveland, was named president-elect. Dr. Toomey is a professor of clinical pediatrics and contagious diseases, Western Reserve University School of Medicine, and physician in charge of the contagious division at City Hospital.

Medical Supplies for War Needy.—The Medical and Surgical Relief Committee of America is making an appeal for funds, drugs, medical instruments and medical and dental literature to be sent to needy and war devastated areas throughout the world. Since June 1940, when it was founded, the committee has shipped $1,220,916 worth of supplies to institutions. All donated supplies are rigidly checked by experts and reconditioned before shipment. Dr. Eugene H. Pool, New York, acting medical director, heads an advisory committee of physicians including Drs. George C. Andrews, Conrad Berens, Russell L. Cecil, Stuart L. Craig, Joseph Felsen, Franz M. Groedel, Ada Chree Reid, Lieut. Comdr. Carnes Weeks, Philip D. Wilson, all of New York; Rear Admiral Ross T. McIntire, Crenshaw D. Briggs and Daniel Blain, Washington, D. C.; Marjorie E. Reed, Plymouth, Pa., and Allen C. Whipple, Rochester, N. Y.

Postgraduate Medicine—A New Journal.—The Interstate Postgraduate Medical Association has begun the publication of a monthly periodical entitled *Postgraduate Medicine*. The first issue contains signed articles together with pictures of several of the authors, an editorial section, a section entitled This Month in Medicine, another entitled Men in Medicine, a consultation service, questions and answers, a correspondence column, Interstate Postgraduate Notes, pictures of historical epics in medicine and of the 1946 meeting of the association, and a section entitled What Other Editors Think. The editor in chief is Dr. Charles W. Mayo, Rochester, Minn., and the managing editor Dr. Arthur G. Sullivan, Madison, Wis. There are also a surgical, a medical and a specialty advisory board.

New England Diabetes Association.—The first meeting of the New England Diabetes Association will be held April 16 at 7:30 p. m. in the Dowling Amphitheater, City Hospital, Boston. The following clinical program will be presented: Drs. Frank N. Allan and Rosemary A. Murphy, Lahey Clinic, Boston, "Diabetes and Hyperthyroidism"; Francis C. Lowell, associate professor of medicine, Boston University School of Medicine, "Relation Between Insulin Sensitivity and Insulin Resistance"; William R. Ohler, assistant professor of medicine, Harvard Medical School, "Diabetic Coma at the Boston City Hospital," and Dr. Stanley L. R. Robbins, assistant pathologist, Mallory Institute of Pathology, Boston, "Renal Disease in Diabetes." A brief business meeting will follow. Physicians, surgeons, nurses, dietitians and other scientific workers interested in diabetes may apply for membership at the meeting or may write to the temporary secretary, Dr. James H. Townsend, 330 Mt. Auburn Street, Cambridge, Mass.

Decline in Mortality from Cancer Among Women.—The Statistical Bulletin of the Metropolitan Life Insurance Company reports a number of hopeful signs in the current cancer picture. Among white females insured in the industrial department of the Metropolitan, the age adjusted death rate from cancer in 1946 dropped to 78.9 per hundred thousand at ages 1 to 74 years, a new low. About ten years ago the rate was 90 per hundred thousand. Even among white male policyholders the mortality for cancer has shown a slight downward tendency. The gains in the control of cancer are likewise reflected, the bulletin states, in the trend of mortality at the various age periods. The largest improvement in the cancer death rate in the last decade among women was 14 per cent, registered among those between 25 and 34 years of age. The least improvement, 2.5 per cent, was recorded at ages 35 to 44. The cancer death rate among white men in the past decade has declined moderately at every age except 45 to 54, where there has been a slight increase. In a tabulation of the figures for this insurance experience, substantial declines are observed in the mortality from cancers of accessible sites between 1941-1945 and 1936-1940: for all such sites combined the decrease in death rate amounted to 15 per cent among white males and 9.8 per cent among white females. For such important sites among females as the breast and the uterus, the declines were 3.9 and 12.8 per cent respectively. Even most of the inaccessible cancers have tended to decline in mortality. Only cancers of the respiratory system and cancers classified in a residual group "others and unknown" have shown an important increase in their recorded death rate. These increases, it is said, are to some extent at least spurious and arise out of improved diagnosis and more accurate reporting. While the recent trend of cancer mortality has encouraging aspects, it would be to misread the facts to conclude that anything beyond the mere beginning has been made toward the control of cancer.

CORRECTIONS

J. W. Scott.—In the leading article in The Journal, March 15, page 735, the name of the third author should have been J. W. rather than G. W. Scott, M.D., Iowa City.

American Surgical Association.—In The Journal, February 1, page 310, in the "History of the American Medical Association" appears a statement to the effect that the American Surgical Association was organized in 1880 and that it was the first society devoted exclusively to specialists. This statement is incorrect since the American Dermatological Association was organized on Sept. 6, 1876 and the American Surgical Association was not organized until May 31, 1880.

Deaths

Donald Cameron Gordon, Scranton, Pa.; born in Ottawa, Ont., in 1895; McGill University Faculty of Medicine, Montreal, Que., Canada, 1922; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; immediate past president of the Lackawanna County Medical Society; served with the Canadian army in France during World War I; began active duty as a major in the medical corps, Army of the United States, in August 1942; served as chief of radiology at Camp Picket, Va., Woodrow Wilson Hospital, Staunton, Va., at a camp in South Carolina and at Fort Leonard Wood, Mo.; service terminated with the rank of lieutenant colonel Jan. 26, 1946; formerly on the staff of the Carbondale (Pa.) General Hospital; on the staffs of St. Mary's Mater Misericordia Hospital, West Side Hospital and the Moses Taylor Hospital; died January 9, aged 52, of cerebral hemorrhage.

Dyer Findley Talley ⊕ Birmingham, Ala.; born in Woodlawn, Ala., in 1865; Medical Department of Tulane University of Louisiana, New Orleans, 1892; member of the Southern Surgical Association and the Birmingham Surgical Society; fellow of the American College of Surgeons; formerly professor of surgery at the Graduate School of Medicine, University of Alabama; member of the founders group of the American Board of Surgery; past president Jefferson County Medical Society and the Medical Association of the State of Alabama; for many years served on the state board of censors and state board of medical examiners; founded the Talley Infirmary; consulting surgeon at the Hillman Hospital; one of the founders of the Norwood Hospital, where he served as attending surgeon and chief of the surgical staff and where he died January 8, aged 81, of pneumonia.

Charles Henry Starkel ⊕ Belleville, Ill.; born in Saint Libory, Ill., July 18, 1862; Rush Medical College, Chicago, 1884; at various times served the St. Clair County Medical Society as treasurer, corresponding secretary and vice president; fellow of the American College of Surgeons; formerly health commissioner of Belleville, member of the state board of health and the Illinois State Historical Society; for many years chief surgeon western division of the Southern Railway Company; past president of the Southern Railway Surgeons' Association; served as chief surgeon of the East St. Louis and Suburban Railway Company and chief surgeon of the Southern Coal, Coke and Mining Company; vice president and for many years member of the board of directors of the First National Bank; formerly affiliated with St. Vincent's Hospital; died February 22, aged 84, of cerebral hemorrhage.

John Harvey Law ⊕ Detroit; born in Detroit, April 19, 1909; University of Michigan Medical School, Ann Arbor, 1933; member of the Michigan State Hospital Association, serving as president in 1946; member of the American College of Hospital Administrators and the Detroit Rotary Club; deputy chief of the office of civilian defense for Detroit during World War II; a collaborating officer of the United States Public Health Service for the state of Michigan; first lieutenant, medical reserve corps, U. S. Army, not on active duty; in 1945 president of the Greater Detroit Hospital Council; at one time assistant physician at the Eloise (Mich.) Hospital for Mental Diseases; director and treasurer of the Grace Hospital, where he served an internship, residency and as assistant director and where he died January 9, aged 37, of carcinoma of the small intestine.

Charles Fairbank Painter, Boston; Harvard Medical School, Boston, 1895; member of the American Medical Association and the American Academy of Orthopedic Surgeons; past president of the American Orthopedic Association; fellow of the American College of Surgeons; formerly dean and professor of orthopedic surgery at the Tufts College Medical School; at one time on the faculty of his alma mater; served during World War I; on the consulting staffs of the Brockton (Mass.) General Hospital, Sturdy Memorial Hospital, Attleboro and Fairview Hospital, Great Barrington; formerly on the staffs of the House of Good Samaritan, Carney Hospital and the Robert Brigham Hospital; served as librarian of the Boston Medical Library; editor of the Yearbook of Orthopedic Surgery; died January 6, aged 77, of pulmonary edema.

John Marvin Ingersoll, Miami, Fla.; born in Youngstown, Ohio, March 11, 1869; Western Reserve University Medical Department, Cleveland, 1893; clinical professor emeritus of otolaryngology at his alma mater; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; served during World War I; colonel, medical reserve corps, U. S. Army not on active duty; formerly on the staff of the Cleveland City and Lakeside hospitals in Cleveland; consultant, St. Francis Hospital in Miami Beach; died January 16, aged 77, of uremia.

Henry Parrott Dulaney, Los Angeles; born at Blount, Tenn., in 1877; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1900; in 1910 appointed assistant surgeon at the National Military Home in Johnson City, Tenn.; subsequently served the homes at Danville, Ill., Dayton, Ohio, Marion, Ind., and again at Johnson City; in 1917 placed in charge of the Pacific branch of the National Military Home, now known as the Veterans Administration Center in West Los Angeles, where he has been stationed for many years and where he died January 25, aged 68, of coronary occlusion and diabetes mellitus.

Harry W. Allen ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; on the staffs of the Maternity Hospital and St. Barnabas Hospital, where he died Dec. 28, 1946, aged 74, of coronary thrombosis.

M. H. Allen, Lafayette, Tenn.; University of Tennessee Medical Department, Nashville, 1893; at one time state senator; died January 9, aged 83, of cardiac asthma.

John Anderson Jr., New York; College of Physicians and Surgeons, Baltimore, 1913; affiliated with the University Heights Sanitarium and the Westchester Square Hospital; died in the Fordham Hospital January 19, aged 58, of hemoperitoneum, following an automobile accident.

Ross Epting Anderson, Jackson, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1922; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Medical Association; served during World War I; on the staffs of the Jackson Infirmary and the Mississippi Baptist Hospital; died in St. Dominic's Hospital January 15, aged 48, of chronic myocarditis.

Charlotte E. Cooke Arnold, North Scituate, R. I.; College of Physicians and Surgeons, Boston, 1893; died recently, aged 86, of arteriosclerosis.

Oscar Frank Baerens, St. Louis; Beaumont Hospital Medical College, St. Louis, 1893; died in the Alexian Brothers Hospital Dec. 31, 1946, aged 76, of cerebral arteriosclerosis.

William Asa Baker, Anna, Ill.; Loyola University School of Medicine, Chicago, 1918; member of the American Medical Association; physician for Community High School Athletics Association and associated with the Chicago and Northwestern Railroad; on the staff of the Anna State Hospital, where he died January 18, aged 57, of cerebral hemorrhage.

Sylvester L. Ballard, Grayling, Mich.; Michigan College of Medicine and Surgery, Detroit, 1905; member of the American Medical Association; served during World War I; at one time commissioner of Bay City; died in the General Hospital, Bay City, January 8, aged 65, of cerebral hemorrhage.

Henry Valentine Bancroft, Blue Mounds, Wis.; Rush Medical College, Chicago, 1885; also a druggist; served as postmaster and village health officer; member of the village board; died January 17, aged 86, of chronic nephritis and coronary occlusion.

Chester LeRoy Barry, Oxford, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; for many years physician to the Maryland division of the Pennsylvania Railroad; served as a member of the board of health and public school board and overseas during World War I; died January 22, aged 72, of hypertension.

Joseph E. Bogar, Rahway, N. J.; College of Physicians and Surgeons, Baltimore, 1892; served for many years as a trustee of the Pennsylvania House of Correction for Women; formerly president of the board of education in Millersburg, Pa.; served as physician and surgeon for the Pennsylvania Railroad; died January 21, aged 75, of cerebral hemorrhage.

Henry Harold Brown, Collegeville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; veteran of the Spanish-American War; died January 18, aged 74, of heart disease.

Mark Atkins Brown ⊕ Cincinnati; Miami Medical College, Cincinnati, 1894; since 1942 professor emeritus of medicine at the University of Cincinnati College of Medicine; fellow of the American College of Physicians; past president of the Cincinnati Academy of Medicine; formerly health officer of Cincinnati; for many years affiliated with the Cincinnati General Hospital; died in the Christian R. Holmes Hospital January 13, aged 72, of cerebral hemorrhage.

William Ridgeway Card, Memphis, Tenn.; Louisville (Ky.) Medical College, 1903; served on the staff of the Tennessee Home and Training School for Feebleminded Persons, Donelson; died in the Baptist Memorial Hospital Dec. 27, 1946, aged 72, of carcinoma of the stomach.

George Lafayette Chamberlain, Eldridge, Calif.; Rush Medical College, Chicago, 1891; served during World War I; affiliated with the Sonoma State Home; at one time medical superintendent of the Home for the Feebleminded and Epileptic, Lapeer, Mich.; died in November 1946, aged 77.

Daniel Robert Chase ⊕ Major, U. S. Army, retired, Orlando, Fla.; Dartmouth Medical School, Hanover, N. H., 1905; served during World War I; entered the medical corps of the U. S. Army as a major on July 1, 1920; retired Aug. 31, 1932 for disability in line of duty; died May 15, 1946, aged 67.

Edith M. Clime-Weber ⊕ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1903; died Dec. 23, 1946, aged 67, of coronary occlusion.

William Harrison Clouse, Canton, Ohio; Bellevue Hospital Medical College, New York, 1885; died in the Aultman Hospital Dec. 28, 1946, aged 90, of cerebral hemorrhage.

Benjamin Miles Deardorff, Clatonia, Neb.; Jefferson Medical College of Philadelphia, 1896; died in Lincoln January 13, aged 74, of uremia.

James Washington Dunn ⊕ Cairo, Ill.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; past president of the Alexander County Medical Society; expert examiner to the Pension Bureau since 1900 and member of the medical advisory board during World War II; on the staff of St. Mary Infirmary, where he died January 10, aged 84, of cerebral hemorrhage.

Ralph Stephen Fisher ⊕ Portland, Ore.; Rush Medical College, Chicago, 1910; served during World War I; on the staff of St. Vincent's Hospital; died Dec. 21, 1946, aged 67, of coronary disease.

Camille Joseph Flotte ⊕ Passed Assistant Surgeon Lieutenant, U. S. Navy, Norristown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1919; entered the U. S. Navy on April 14, 1921; retired Jan. 1, 1931 for incapacity resulting from an incident of the service; died January 5, aged 51, of cerebral hemorrhage.

James LeRoy Foster, Pittsburgh; University of Pittsburgh School of Medicine, 1913; member of the American Medical Association; specialist certified by the American Board of Pediatrics; on the faculty at his alma mater; on the staffs of the Children's and St. Margaret Memorial hospitals; medical director of the Juvenile Court; died January 16, aged 58, of coronary occlusion.

Marc A. Fournier, Sault Ste. Marie, Mich.; Michigan College of Medicine and Surgery, Detroit, 1891; died January 15, aged 77, of carcinoma of the stomach.

James Thomas Fowler, Birmingham, Ala.; Medical College of the State of South Carolina, Charleston, 1883; member of the American Medical Association; at one time associated with the Jefferson Manly Falkner Soldiers Home of Alabama in Mountain Creek; died January 8, aged 83, of cardiorenal disease.

Thomas Edward Galvin, Boston; College of Physicians and Surgeons, Boston, 1908; died January 18, aged 73, of cerebral hemorrhage.

Carroll Hunter Gerry ⊕ Shrewsbury, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; died Dec. 24, 1946, aged 70, of *myocarditis and arteriosclerosis.*

Calogero Giovinco ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1900; an Affiliate Fellow of the American Medical Association; on the staff of the Bushwick Hospital; died January 1, aged 77, of cerebral hemorrhage.

Justin Frank Grant ⊕ Boston; Johns Hopkins University School of Medicine, Baltimore, 1903; formerly professor of anatomic embryology and histology at the Atlanta College of Physicians and Surgeons and professor of anatomy and pathology at the West Virginia University School of Medicine, Morgantown; died in Manchester, N. H., January 26, aged 69, of heart disease.

James Alexander Grizzard ⊕ Drewryville, Va.; Baltimore Medical College, 1906; president of the Southampton County Bank; died in the Raiford Memorial Hospital, Franklin, January 28, aged 65, of lymphatic leukemia.

Mercer Freeman Hall, Neligh, Neb.; Ensworth Medical College, St. Joseph, Mo., 1901; died in Cedar Rapids Dec. 14, 1946, aged 75, of chronic myocarditis.

Howard Eugene Hamilton ⊕ Cleveland; University of Kansas School of Medicine, Kansas City, 1934; served a residency and internship at the City Hospital; served a residency at the University Hospitals; specialist certified by the American Board of Otolaryngology; clinical instructor in otolaryngology at the Western Reserve University School of Medicine; died Dec. 27, 1946, aged 35, of cerebral embolus and rheumatic heart disease.

Vallandingham Hawkins, Fawn Grove, Pa.; Baltimore Medical College, 1894; member of the American Medical Association; died Dec. 13, 1946, aged 82, of carcinoma.

James Wallace Hill, Lebanon Junction, Ky.; University of Louisville Medical Department, 1909; died in the King's Daughters' Hospital in Frankfort, January 27, aged 70, of arteriosclerotic heart disease and multiple myeloma.

Perez Briggs Howard ⊕ Newtonville, Mass.; Harvard Medical School, Boston, 1902; served during World War I; died January 18, aged 70, of coronary thrombosis.

Trent Orin Huff, Clinton, Tenn.; University of Tennessee College of Medicine, Memphis, 1934; member of the American Medical Association; formerly prison physician at Petros; died in Macon, Ga., January 6, aged 45, of cerebral hemorrhage.

Samuel Henry James ⊕ San Fernando, Calif.; Chattanooga (Tenn.) Medical College, 1906; member of the Medical Association of the State of Alabama; served during World War I; member of the American College of Chest Physicians; formerly associated with the U. S. Public Health Service Reserve; for many years affiliated with the Veterans Administration Hospital at San Fernando; died Dec. 15, 1946, aged 66, of cerebral hemorrhage.

William Daniel James ⊕ Hamlet, N. C.; Jefferson Medical College of Philadelphia, 1908; member of the House of Delegates of the American Medical Association, 1926-1927; formerly secretary-treasurer of the North Carolina State Board of Medical Examiners; past president of the Richmond County Medical Society; chief surgeon for the Seaboard Air Line Railroad; founder and chief surgeon of the Hamlet Hospital; died January 15, aged 61, of coronary thrombosis.

Kyle McCue Jarrell ⊕ Beckley, W. Va.; University of Maryland School of Medicine, Baltimore, 1906; served as president and secretary of the Raleigh County Medical Society; served one term as deputy sheriff of Raleigh County; vice president of the Beckley National Bank; for many years superintendent of the Pinecrest Sanitarium; died January 24, aged 65, of cerebral hemorrhage.

Charles Kneller Koones ⊕ Washington, D.C.; Columbian University Medical Department, Washington, 1887; died January 14, aged 80, of coronary heart disease.

Charles A. Gottlieb Langner Jr., Brownsville, Texas; Johns Hopkins University School of Medicine, Baltimore, 1928; served during World War II; killed January 12, aged 46, in a plane crash.

Joseph Antonio La Palme, Webster, Mass.; Tufts College Medical School, Boston, 1925; member of the American Medical Association and the Connecticut State Medical Society; fellow of the American College of Surgeons; interned at St. Vincent Hospital in Worcester; a lieutenant commander in the medical corps of the U. S. Naval Reserve during World War II; served on the staff of the Day Kimball Hospital in Putnam, Conn.; died January 21, aged 46, of coronary thrombosis.

Charles Francis Lawler, Detroit; Milwaukee Medical College, 1907; member of the American Medical Association; served on the staffs of the Pontiac (Mich.) General Hospital and St. Joseph's Mercy Hospital; died January 13, aged 70, of cerebral hemorrhage.

Fred Allard Lemar ⊕ Columbus, Neb.; University of Nebraska College of Medicine, Omaha, 1902; served during World War I; on the staff of St. Mary's Hospital, where he died January 2, aged 72, of heart disease.

Louis Levin ⊕ Trenton, N. J.; Jefferson Medical College of Philadelphia, 1919; served as cardiologist to St. Francis Hospital, State Hospital and State Prison; author of "Living Along with Heart Disease" ; died January 1, aged 49, of cerebral thrombosis.

Walter C. Lovejoy ⊕ Maywood, Ill.; Chicago Homeopathic Medical College, 1891; fellow of the American College of Surgeons; past president of the Aux Plaines Branch of the Chicago Medical Society; charter member and past president of the Maywood Rotary Club; veteran of the Spanish-American War; affiliated with the Westlake Hospital, Melrose Park, where he died January 15, aged 79. of coronary occlusion.

Thomas C. McGonagle, Chicago; Northwestern University Medical School, Chicago, 1898; member of the American Medical Association; at one time on the faculty of his alma mater; on the staff of the Evangelical Hospital; died January 31, aged 79, of seminoma of the testes.

Charles MacGregor ⊕ Dayton, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; died January 21, aged 78, of cerebral hemorrhage.

Francis Aloysius McMullin, Philadelphia; Jefferson Medical College of Philadelphia, 1901; died January 28, aged 67, of bronchopneumonia.

Irving Oliver Mahr, Boyertown, Pa.; Temple University School of Medicine, Philadelphia, 1912; served overseas during World War I; died in St. Joseph's Hospital, Reading, January 11, aged 56, of coronary embolism.

Philip Manjoney, Central Islip, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1916; served a residency at the Central Islip State Hospital, where he died January 3, aged 57, of adenocarcinoma of the cecum.

Howard Longstreet Maps ⊕ Budd Lake, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1909; at one time practiced in Passaic, N. J., where he was affiliated with St. Mary's Hospital, serving for many years as president of the staff, and Passaic General Hospital; died in the Morristown (N. J.) Memorial Hospital January 18, aged 61, of coronary thrombosis and cerebral embolus.

Raymond Victor May, Cleveland; University of Wooster Medical Department, Cleveland, 1913; specialist certified by the American Board [illegible] r of the American Medical Association, the [illegible] of North America, Inc., the Academy of [illegible] and the American College of Radiology; for many years on the staff of St. Luke's Hospital; died Dec. 27, 1946, aged 56, of cancer of the pharynx and diabetes mellitus.

John Artemas Mead ⊕ Hattiesburg, Miss.; Mississippi Medical College, Meridian, 1912; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; formerly practiced in Logtown, where he served as health officer of Hancock County; member of the medical reserve corps during World War I; during World War II examining physician for Selective Service, Forrest County; awarded a presidential citation; died February 10, aged 62, of coronary thrombosis.

Robison E. Michener, Mulvane, Kan.; Eclectic Medical Institute, Cincinnati, 1899; served as a member of the city council and the school board; died in the Wichita (Kan.) Hospital January 10, aged 85, of bronchopneumonia.

Charles Donley Miller ⊕ Syracuse, N. Y.; Hahnemann Medical College and Hospital, Philadelphia, 1921; served during World War I; medical director of the Unity Life Insurance Company; died January 8, aged 51, of hypertensive heart disease.

Wilfred Porter Miller, Syracuse, N. Y.; University of Maryland School of Medicine, Baltimore, 1917; member of the American Medical Association; served on the staffs of the Syracuse General and St. Joseph's hospitals; died January 16, aged 61, of coronary disease.

Samuel Cargill Milligan, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1891; member of the American Medical Association; veteran of the Spanish-American War; on the staff of the South Side Hospital; died January 4, aged 85, of cerebral hemorrhage.

William Elias Mills, Sumter, S. C.; Medical College of the State of South Carolina, Charleston, 1901; honorary member of the South Carolina Medical Association; member of the American Medical Association; on the staff of the Toumey Hospital, where he died January 6, aged 70, of coronary thrombosis.

Byron Fay Mock, San Diego, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1925; member of the American Medical Association; died January 3, aged 47, of coronary artery disease.

Benjamin Henry Morris, Tucson, Ariz.; Cornell University Medical College, New York, 1943; interned at the Bellevue Hospital in New York, where he served a residency at the Doctors Hospital; diplomate of the National Board of Medical Examiners; died January 9, aged 31, of coronary thrombosis.

Guy Guerdon Newton, Evergreen, Ala.; Medical College of Alabama, Mobile, 1897; member of the American Medical Association; died January 15, aged 73, of influenza and bradycardia.

Frank Nisbett, Brookland, Ark.; Memphis (Tenn.) Hospital Medical College, 1905; member of the American Medical Association; died in Jonesboro January 11, aged 74, of myocarditis and nephritis.

Eugene E. Northcutt ⊕ Newport, Tenn.; Vanderbilt University School of Medicine, Nashville, 1904; medical superintendent of the Dr. E. E. Northcutt Private Clinic and Infirmary; died in St. Mary's Hospital, Knoxville, Dec. 23, 1946, aged 66, of carcinoma.

Charles O'Leary, Providence, R. I.; Long Island College Hospital, Brooklyn, 1893; died January 3, aged 77, of chronic nephritis.

Lewis N. Osborne, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1898; died January 15, aged 77, of cerebral vascular disease.

Ray Charles Otte ⊕ Wellsburg, W. Va.; Western Reserve University School of Medicine, Cleveland, 1929; on the staff of the Ohio Valley General Hospital, Wheeling, where he died recently, aged 42, of carcinoma.

Guy Mannering Owsley, Thorntown, Ind.; University of Louisville (Ky.) Medical Department, 1905; formerly a member of the school and library boards; died January 18, aged 64, of carcinoma.

Charles Pius ⊕ Yreka, Calif.; Cooper Medical College, San Francisco, 1906; served during World War I; served as city health officer and as superintendent of the Siskiyou County General Hospital; died January 9, aged 65, of coronary occlusion.

William Edward Quicksall ⊕ St. Petersburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; at one time on the faculty of his alma mater and on the staff of St. Joseph's Hospital in Philadelphia; on the staff of the Mound Park Hospital, where he died January 13, aged 70, of cerebral hemorrhage.

Richard Gilchrist Smith ⊕ Denver; University of Colorado School of Medicine, Denver, 1912; assistant professor of surgery (urology) at his alma mater; member of the American Urological Association; specialist certified by the American Board of Urology; affiliated with the Colorado General Hospital, Swedish National Sanatorium and Denver General Hospital, where he formerly was president of the staff, and the Mercy Hospital, where he died Dec. 9, 1946, aged 65, of coronary artery disease.

Richard Manges Smith ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1927; specialist certified by the American Board [illegible] of the American Roentgen Ray Society [illegible] of North America and the American [illegible] demonstrator of radiology at his alma [illegible], 1946, aged 45, of multiple sclerosis.

Sam Sparhawk, Ypsilanti, Mich.; University of Vermont College of Medicine, Burlington, 1926; member of the American Medical Association and the Vermont State Medical Society; served during World wars I and II; in 1946 placed in charge of the Lewis-Pacific Counties Department of Health in Washington; died in the University Hospital, Ann Arbor, January 22, aged 47, of acute peritonitis.

Dillon J. Spotswood, Mobile, Ala.; Medical College of Alabama, Mobile, 1890; died Dec. 1946, aged 82, of accidental suffocation.

H. A. Stuart, Olive Branch, Miss.; Louisville (Ky.) Medical College, 1894; died Dec. 23, 1946, aged 78, of cerebral hemorrhage.

Claude W. Trapp, Lexington, Ky.; University of Louisville (Ky.) Medical Department, 1889; member of the American Medical Association; died in St. Joseph's Hospital January 18, aged 79, of gangrene of the left leg.

Henry Benjamin Watson, Miami Beach, Fla.; University of the City of New York Medical Department, New York, 1888; for many years affiliated with the Metropolitan Life Insurance Company in New York; died Dec. 19, 1946, aged 82, of carcinoma of the prostate.

Jacob Allen Wells ⊕ Paintsville, Ky.; University of Louisville School of Medicine, 1911; served as president of the Johnson County Medical Association; died in St. Mary's Hospital, Huntington, W. Va., February 22, aged 66, of coronary occlusion.

John G. Wilkinson, Birmingham, Ala.; University of Tennessee Medical Department, Nashville, 1902; member of the American Medical Association; died January 8, aged 79, of pulmonary embolism.

David Zuckerman ⊕ Brooklyn; University and Bellevue Hospital Medical College, New York, 1910; founder, member of the board of directors and chief proctologist at the Crown Heights Hospital; died January 24, aged 60, of coronary thrombosis.

More Education for Nurses

The council of the Royal College of Nursing has decided to set up a separate educational establishment. If possible there will be a school within the University of London, and the opportunity will be examined of providing nursing education at both postgraduate and undergraduate levels in addition to diploma courses. University schools of the type envisaged already exist in the United States, Canada and India. In an editorial the *Nursing Times* states that if the universities and nursing profession in this country do not follow that lead British nurses will be unable to compete for the higher nursing posts in the Dominions, colonies and other countries, as they will have no experience of the advanced nursing education at the university level that the rest of the world is beginning to demand.

It is not claimed that a university degree is needed by all nurses. Much simple nursing care can be carried out efficiently and intelligently by any woman of average ability who wants to look after the sick. But the constant advances of medicine and surgery have thrown increasingly technical work on nurses. The British universities have not opened their doors as readily to the technical professions as those of the United States and are stricter in their demands for educational standards of entrants. The Royal College of Nursing does not ask for the lowering of these standards nor does it wish to decrease the prestige of the degree conferred. But, it asks for broadening of the educational facilities within the University of London to secure the position of the British nurse throughout the world.

Rehabilitation Following Chest Surgery

At the Section of Physical Medicine of the Royal Society of Medicine Mr. Holmes Sellor discussed the special subject of rehabilitation following chest surgery, which he said was better in chest than in general surgery, if only because the treatment of chest cases was carried out in institutions where the general tempo of life was more like that of a sanatorium than of a busy city hospital. In chest work the aim was to keep the patient in the hospital until he was ready to return practically to a normal life. Some stayed only four or five weeks in the hospital, but the difficult ones were those with chronic empyema and those with complications, who might have to remain for periods up to a year. Diet had to be considered, as in suppurations the loss of protein might be considerable. The most difficult problem was the psychologic one of the patient in the hospital, for as he improved he became restless and later apathetic. The best example of the long term case was chronic empyema, in which a mass of fibrin was deposited over the pleural surfaces surrounded by an unyielding contracted chest wall. Secondary scoliosis was an appalling deformity often the result of maltreatment in the acute stage.

Chest Exercises

The object was to get the chest wall moving and to prevent any structural deformity from developing. The type of breathing exercise was thus based on inspiration. These inspiratory exercises were new, but physical therapists, who had developed them, had shown their inestimable value. The first secret was the teaching of concentration. Breathing exercises for ten minutes each morning were useless. The patient should be told that of the twenty-four hours eight were sufficient for sleep, eight were enough for meals and play, and the remainder should be given to sedulous training in breathing. He should be taught localized inspiratory exercises, working against some form of resistance, concentrating his mind and activity on the area of chest that it was desirable to move. In empyema it was the basal expansion which was important to regain. By careful concentration it was possible to move one area and only one by voluntary efforts. Other movements were lateral movements, an attempt to get posterior expansion and finally a ripple almost along the anteroposterior line.

After general exercises it was important to see that the stance of the patient and his position in bed were correctly maintained. There was a tendency to avoid discomfort in bed by cramping-in on the bad side of the chest, which actually tended to increase the defects which it was sought to remedy. In the absence of contraindications the patient should be got out of bed, as effective coughing for clearance of secretions was most desirable. For occupational therapy leather work and toy making had proved their value.

A Biography of Sir Jonathan Hutchinson

Though Sir Jonathan Hutchinson, noted as a clinician, died in 1913, his biography, written by his nephew, has only just appeared. On his death many important obituary notices from eminent friends in different branches of the profession (so widely was his work revered), from the ophthalmologist Nettleship, from the surgeon Sir Rickman Godlee and from the physician Sir Thomas Barlow, none dealt adequately with his private life or his general, as apart from his medical, teaching. None of the writers had access to the mass of private letters, particularly those to his wife, which reveal his deepest thoughts. Not being medical, the author asks the profession not to expect medical knowledge on his part. However, he has made good use of the pronouncements from leading men, both at home and abroad, on Hutchinson's work. A surgeon, Mr. J. Johnston Abraham, contributes an interesting foreword telling of his first contact with Hutchinson at the Polyclinic, which he founded for postgraduate teaching after retiring from the active staff of the London Hospital: "A tall bent old man with a great dome of a head, dark eyes looking benevolently through steel rimmed spectacles. Round him he had grouped rows and rows of colored pathologic drawings, mostly of rare skin diseases. He spoke rather slowly and solemnly, and what he said was clear and logical. There was nothing scintillating about it, but you felt he was speaking out of an immense knowledge. Occasionally he illustrated his point by some unexpected simile."

A Clinician with Breadth of View

Mr. Hutchinson begins with the family history and pedigree of his uncle. The family had been Quakers since the origin of that sect, and one of them suffered imprisonment for his faith. With such an upbringing Sir Jonathan Hutchinson remained a deeply religious man. But his knowledge of science, and particularly the doctrine of evolution as expounded by Darwin, modified his views. He accepted evolution with enthusiasm, as it enlarged his hopes for the future of humanity. "The attempt to realize heavenly life on earth" became his religion. The author asks his readers to accept this book "as embodying a very definite message for our generation. Not a theory merely but a life, inspired by a conscious purpose." To the medical readers the book will have a special appeal as a complete revelation of the deepest thoughts and private life of the greatest clinician of his age, a specialist in many fields who, in contrast to the narrowness of outlook associated with that class, always had a breadth of view which can only be described as philosophical. He saw the normal and the abnormal, the common and the rare, science and religion, as one entity.

Ruptured Intervertebral Disk Simulating Angina Pectoris

The work of Josey and Murphey recorded in THE JOURNAL, June 15, 1946, has had a noteworthy reception in Italy and also in France. The *Presse médicale* of February 5, page 91, points out that it is a work which should attract the attention of the medical profession. Two typical instances occurred in employees of a large Italian street car company. Following a vertebral traumatism sustained in the collision of two vehicles the angina syndrome was apparent from reactions to the more physical effect of walking, though electrocardiographic examination proved negative. A myelogram afterward showed a protrusion of the herniated nucleus pulposus in one of the cervical vertebrae. A radiologist, a surgeon and a pathologist have recently written on the pathology of the annulus fibrosus and the protrusion of the herniated nucleus pulposus, a topic which has been followed in Italy with great interest. The work is presented by a noted neurologist and is compiled by Drs. Imperati, Muscettola and Rubino. Eight cases of hernia of the disk with symptoms varying from lumbago to sciatica are reviewed, all caused by accidents involving injury though the patients were unaware of them at the time or had forgotten them. These cases have been verified by radiography, with the myelogram. The authors have employed surgical therapy but state that they do not share the enthusiasm shown in other countries for this kind of treatment. According to them the "primum movens" more than the injury which causes the hernia of the intervertebral disk is constitutional and depends on the arthritic disposition of the patient. Therefore before resorting to surgical operation they tried a general disintoxicating therapy and hygienic thermal bath treatment. Led to believe that no better means could be applied, they followed the surgical course of treatment only in severe cases as the results were discouraging.

Nobel Prize Winner Chain in Italy

Dr. E. B. Chain, chemist and Nobel Prize winner, and member of the famous team which worked on the discovery of penicillin, has arrived in Italy at the invitation of the Antibiotic Study Center to lecture in Naples, Rome, Florence and Venice. A few months ago Professor Fleming, the honorary president of the Italian Antibiotic Study Center, came to Milan and lectured on the same subject. Dr. Chain, who was received by the chancellor of the University of Naples and all the representations of the Faculty of Medicine, commenced his tour by giving a lecture in the Great Hall of the university. A large number of doctors, physicians and chemists attended. Chain recounted the story of the discovery of penicillin and then went on to discuss the chemical constitution of the molecule of penicillin. He discoursed on a few of the difficulties now being encountered in the attempts being made to produce penicillin synthetically. He clearly pointed out the general differences in antibacterial properties between penicillin and sulfonamides, though he did not hide the fact that the "antibiotic action" remains obscure in many ways. He discussed the case of initial inadequate doses of penicillin during treatment; save for certain bacterial bodies, the drug—notwithstanding bacterial resistance—could become again effective by increasing the doses. Chain however was rather skeptical on the possibilities attached to synthetic penicillin. He widely praised the admirable progress made in the production of the natural product, and particularly with regard to the American industry. He seems to be of the opinion that the supply of natural penicillin will eventually be sufficiently great for world needs and much more economical than the future synthetic product, owing to difficulties of preparation. In an interview Dr. Chain was asked about the different groups of penicillin, viz. F, G, X and K, which he referred to in English terminology as 1, 2, 3 and 4. He stated that K penicillin is easily destroyed by serum of the circulating blood and that it is for this reason that though active in vitro it is less valuable than, for example, penicillin G, the composition of which makes it a more perfect preparation and depends on the chemical constitution of the medium in which it is grown. Chain appeared a genial and great scientist. He insisted, with great affability of manner, that the Italian Bartolomeo Gosio should rather be remembered as a pioneer of the antibiotic drugs. Gosio in 1893 had already isolated Penicillium glaucum in crystalline form—the more common form of mold derived from maize. This discovery, according to Chain, was the first memorable date in the story of penicillin.

SWEDEN

STOCKHOLM, March 11, 1947.

Nurses Request Higher Pay

The public is taking great interest in the present fight of nurses versus the government, brought about by the refusal of the government to increase the nurses' pay. An unusually large audience attended the recent meeting of the Swedish Nurses' Association at one of the bigger auditoriums in Stockholm. Every seat was taken, and many people had to be turned away, for the "opinion" meeting promised to be lively. The nurses rose up in holy wrath and had their say on many abuses within the profession, particularly the long hours and underpay. Instead of going on strike, of which there had been rumors, the nurses of the three state hospitals in Stockholm announced that they would resign in a body but stay on the jobs as their own substitutes at a better and fairer rate of pay than they were now receiving as regular employees. The speakers directed strong criticism against the government and demanded better working conditions and no more working on an assembly line basis. One nurse told the audience of the situation at the Serafimer Hospital where 80 male and 300 female patients were waiting to be admitted to the neurosurgical clinic. Owing to the shortage of nurses one entire section has had to be closed, and the waiting period for some patients is as long as two years. The situation in the city of Stockholm hospitals is somewhat better than in the federal, although there also the shortage is strongly felt, and it is almost impossible for them to get nurses aides or student nurses. One hospital has taken to offering cleaning jobs to patients who have recovered and thereby gained some extra working help. The fight is still going on with the public in sympathy with the nurses.

Nordic Surgical Congress in June

The Nordic Association of Surgeons plans to hold its congress in Stockholm from June 26 to 28 and in conjunction therewith celebrate the fiftieth year of its existence. This should actually have taken place in 1943 but had to be postponed because of the war. The Nordic Orthopedic Association will simultaneously hold its first meeting since the war. It is estimated that about 300 surgeons and orthopedists will attend, 100 from Sweden and the remainder from the other Scandinavian countries.

Swedes Help Fight Venereal Disease in Poland

Venereal disease has been on the increase in Poland ever since the war, especially in Masuria, where almost entire villages are contaminated. To help fight this alarming situation a "venereal ambulance" was outfitted by the Swedish Red Cross with the help of a grant of 100,000 kronor from the Help to Europe fund. This ambulance left Sweden recently to spend first three months in Masuria and then travel farther through Poland. A Polish physician, Dr. Josefina Pietrowska, a Swedish nurse and assistant, two Swedish chauffeurs and a jeep made up the party. This big white polyclinic on wheels is the first of its kind in Sweden. It is a 90 horse power Volvo military bus converted into a waiting room, a treatment room and a sterilizing room. All the equipment is said to be of the finest quality. It is expected that about 100 patients a day will be given prophylactic treatment in Poland. The more severe cases will of course have to be sent to stationary hospitals.

Three Babies Die of Tetanus from Infected Talc

Details of the investigation of the fatal illness of 3 babies in Auckland, New Zealand, within a fortnight, have been reported by the New Zealand Department of Health. The investigation began after the death of the first two babies, who were about a fortnight old. The umbilical stump was septic in both cases. One child had been circumcised, but the surgical wound was clean. It appeared that all dressings had been autoclaved, and the only common factor in the nursing of the two babies was the talc used in their toilet. This proved to be made from talc imported from India in unlined jute sacks. The process of manufacture consisted in mixing with perfume and a small portion of boric acid. The third case occurred a week later, and in this, one of the same brands of powder had been used In spite of the prompt administration of antitetanic serum and penicillin, all 3 babies died. In their case history, particular mention was made of the high degree of muscular spasm in each child and also the hyperpyrexia. The presence of tetanus spores in the infected talc was proved. This form of the silicates of magnesium is found in natural deposits which are quarried or mined, and it is not surprising that contamination with tetanus should occur. Samples of French chalk arriving in New Zealand in previous years have been found to be infected with the spores of Clostridium tetani. The sites where these forms of magnesium silicate are obtained have been used over a very long period and are possible sources of contamination by animal feces. Cultivation of the specimens of talc by the method of Fildes was successful in isolating the organism. The appearance of spores in a culture is not always certain, as it depends on several factors, including the selection of culture medium. A culture may consist of filamentous forms and yet produce a subculture of sporing forms. The organisms isolated from the talc were proved to be virulent for animals. Swabbings from the umbilicus were also examined from each baby, but isolation cultures were not successful. As soon as the disease was recognized, prompt action was taken to withdraw the suspected powder from the market, and precautions for sterilization of talc were instituted. In future, all talc will be sterilized before retail marketing.

Proposed National Pharmaceutical Benefits Scheme

The commonwealth government is considering plans for the introduction of a national pharmaceutical benefits scheme. This is popularly known as "free medicine." Pharmacists are willing to cooperate, provided certain principles affecting their rights are not interfered with. Agreement had practically been reached last year on terms of service, but negotiations were suspended because of the potential threat in certain clauses of the bill which enabled "Friendly Societies" dispensaries to conduct pharmacies and trade generally with the public. Conditions have changed since last these matters were discussed between government representatives and pharmaceutical leaders. The commonwealth now has extra powers, conferred by the recent referendum, and is in a strong position for negotiation. The pharmacists do not wish blindly to obstruct the government's scheme solely because it is a national scheme. Their promise of cooperation was withdrawn because of spontaneous resistance to an action which strikes at one of the fundamentals of pharmaceutical practice—the preservation of their personal and individual rights with regard to the practice of their profession. Pharmacists see a danger that the individual pharmacist will be crushed by group interests—a real menace as one can see from the examples in recent history of the crushing of the small man by cooperative societies, chains and other monopolist trading associations. The pharmacists will resist strongly such encroachment on their rights of private practice. A splendid private service has been given in Australia, and there is no doubt that an equally good national service can be provided by retail pharmacists in cooperation with the commonwealth. Action by the government which would result in the elimination of independent practice by professional men and small traders would be in direct negation of the Labor government's policy, so it is unlikely that the government will force an issue that could not fail to lead in that direction. The minister of health recently met the federal executive of the Pharmacist's Guild to reopen discussions on the Pharmaceutical Benefits Act. These will have an important bearing on the future of pharmacy in this country.

Investigation of Health Services in South Australia

A committee was appointed by the Parliament of South Australia to inquire into and report on the advisability of consolidating the health services of the state into a single department under the minister of health. Four of the seven members of the committee were doctors. Its report was submitted to Parliament on Dec. 4, 1946. The committee found that, in general, the existing organization is a patchwork lacking consolidated statutory control. There is no proof that the work is coordinated into a competent medical service. The functions of the different bodies overlap, and there is lack of liaison between them.

The investigation revealed that the public health machinery of South Australia is still based on the health act of 1898. The health services of the state are divided into two main groups, both under the control of the minister of health. Health services are administered by a central board of health and medical services by the director general of medical services through the channels of the Hospitals Department. The only liaison between the two is an Advisory Committee on Health and Medical Services appointed by the government in 1943. This committee advises the minister of health on health services. There are, however, certain health services not under the control of the minister. It is the responsibility of the Central Board of Health to administer acts of Parliament relating to the various health activities in conjunction when necessary with the Metropolitan County Board and the various local boards of health, of which there are in the state no fewer than 142. The Hospitals Department is controlled by the director general of medical services, who is responsible to the minister of health for the control and administration of hospitals and institutions, which may be classified as government general hospitals, tuberculosis hospitals and mental hospitals.

The Parliamentary Committee recommended that a Department of Health and Medical Services should be established under the control of the minister of health and that a commission to be known as the Commission of Health and Medical Services should also be appointed to control and administer the department and be responsible to the minister, the commission to consist of five members, of whom the chairman would be director general of health and medical services. He should be a medical practitioner and a permanent full time officer of the public service. Two of the remaining members should also be medical practitioners. These proposals are in accordance with the principles held by the South Australian Branch of the British Medical Association. It seems that the government of South Australia is in earnest about the state of its health services and that it will plan wisely for the future. Much will depend, particularly in the initial stages, on the man who is chosen as medical head of the proposed commission.

Correspondence

OBESITY

To the Editor:—Dr. S. Charles Freed, in his article on "Psychic Factors in the Development and Treatment of Obesity" (The Journal, February 8, p. 369) has emphasized the important psychologic aspects which have often been overlooked. The problem of obesity cannot simply be approached in mechanistic terms of "glandular balance." Dr. Freed has enumerated many more dynamic factors which are essential for a thorough evaluation of the complexity of etiologic factors of obesity. There is, however, also a great danger associated with this type of psychodynamic approach, which has again and again been stressed by our leading clinicians. It concerns the problem of causality and constitution. Psychosomatic concepts must be based on the fundamental question Are emotional factors truly etiologic agents or are pathophysiologic developments and personality characteristics both parallel processes, depending on inherent constitutional qualities?

Dr. Freed has completely omitted to mention the constitutional aspects of obesity. One should not overlook the significant contributions of Constitutional Clinics and the studies by George Draper, Julius Bauer and William Sheldon. According to Draper "General metabolism and body weight are inextricably bound up in the individual constitution of the person, and no broad understanding of the problem can be developed unless it is based on a knowledge of the individuality of each person's body build and energy characteristics." And Bauer says "All obese persons must have a certain individual predisposition, that is, they must have a weight regulating mechanism which is more readily overthrown than the normal one. All cases of obesity are to variable extent endogenous and constitutional in origin."

Being a psychiatrist, I am certainly sympathetic toward Dr. Freed's approach To be scientific, however, I believe one has to be careful with regard to evaluating causality principles in psychosomatic medicine. No therapy can be rational which is not based on sound recognition of constitutional potentials. No psychotherapy of obese patients has good prospects if constitutional limitations are ignored or overlooked.

F. A. Freyhan, M.D., Wilmington, Del.

[The letter of Dr. Freyhan was referred to Dr. Freed, who writes:]

To the Editor:—I am in agreement that there is a constitutional aspect to the development of obesity, so that there is in many persons an inherent tendency in this direction. I do, however, disagree that I failed to mention completely these principles. Perhaps I used different terms, but certainly from the following quotations there is a definite implication that such states exist:

"Human machines like other machines differ in efficiency, and the metabolically efficient human body will gain weight on the same intake of food on which the inefficient one will lose weight."

"It is not considered that these factors are specific causes for overeating, but simply they release the nervous energy into the channel of overeating in those persons who tend in that direction. The same psychic factors will produce in other subjects various types of psychosomatic disorders."

I do not list the psychic factors as causative or etiologic for the production of overweight, but rather inciting stimuli in individuals who tend in that direction. Certainly the inability of a patient to restrict the food intake to the proper level, whatever that may be, is purely an emotional problem. The difficulty in restraining the appetite is enhanced by the variety of psychodynamic drives associated with nervousness, social insecurity, childhood training and the like.

S. C. Freed, M.D., San Francisco.

[To this Dr. Freyhan comments:]

To the Editor:—If I may take the liberty to disagree with Dr. Freed's reply, it is for the simple reason that certain fundamental issues are under discussion.

My position is, I believe, identical with the ideas expressed by Drs. George Wilson and Charles Rupp in their article "Present Trends in the Practice of Neurology" in The Journal, February 22. Both doctors sharply criticize present trends in psychosomatic medicine, saying ". . . it appears that, save for a few isolated exceptions, most of the psychosomaticists have become too preoccupied with the aspects of the psyche, to the neglect of the soma."

Dr. Freed has not at all stressed constitutional aspects of obesity. His references to predispositions are vague and obscured by overemphasis of psychogenic factors. The fundamental problem is whether emotional problems per se, even as "inciting stimuli," cause obesity unless there is already an inherent, constitutional disposition. The term "constitution," which clinicians consider primarily essential in the problem of obesity, is never mentioned in Dr. Freed's article. His article conveys the impression that a psychiatric approach to the emotional problems of the obese individual is the primary therapeutic problem. This assumption, I feel, is not justified, because the constitutional potential limits a priori psychotherapeutic efforts.

The psychiatric profession, of which I am an enthusiastic member, should welcome the criticism of Drs. Wilson and Rupp and demand that psychosomatic studies be based on sound principles of internal medicine as well as psychodynamics.

F. A. Freyhan, M.D., Wilmington, Del.

PERMANENCE OF FOOTPRINTS

To the Editor:—I should like to draw your attention to a gross error in the article by Dr. Hyman published in The Journal for Dec. 7, 1946. Dr. Hyman's statement that the footprints of infants taken at birth are useless because they "change after a few months" and therefore are of no value in later establishing the identity of a person shows that Dr. Hyman has no understanding of structure and development of the dermal ridges. Skin patterns are established at the third and fourth fetal months, and from that time throughout life there is no significant alteration in the details of the ridges and the patterns they form. Dr. Hyman is perhaps under the misapprehension that the footprints record only the creases or folds of the skin, which of course do change.

It is quite true that in many institutions the footprints of infants are so poorly made that the dermal patterns are undecipherable. It is therefore important that medical attendants or nurses should be properly trained to take and to read the dermal patterns of both soles and palms.

Norma Ford Walker, Toronto.
Associate Professor of Human Biology, University of Toronto Department of Zoology.

NATIONAL DEPARTMENT OF HEALTH

To the Editor:—Referring to your copy of S. 545, it seems to me that the main thing is overlooked and that, to my mind, would be the creation of a department of health with a cabinet officer at the head of it. I believe we are about the only civilized people who do not have a minister of health. I do not imagine that the other departments, such as State, Treasury and Commerce, are governed by any such long complicated bill as S. 545 and a department of health could run without such minute directions.

Edward C. Ellett, M.D., Memphis, Tenn.

Medical Motion Pictures

FILM REVIEWS

Convalescent Care and Rehabilitation of Patients with Injury to the Spinal Cord. 16 mm., color, sound, 1,550 feet (1 reel), showing time forty-three minutes. Produced in 1946 by the Medical Department, U. S. Army. Procurable on loan from Office of the Surgeon General, U. S. Army, Pentagon Building, Washington, D. C. Attention: Chief of the Division of Education and Training.

This excellent picture presents the story and the care of the paraplegic patient from the time he is flown to a general army neurosurgical center until he leaves, walking on his splinted legs. The extraordinary facilities of a technical nature are clearly demonstrated; nowhere else can so much technical pressure be brought to bear for the benefit of the patient. There is some extraneous matter at the beginning dealing with the visits of relatives and the understandable emotional strain which is concomitant with wounds of this type. The first consideration is an evaluation of the patient's general and neurologic condition, and this is adequately shown. There is a short section on the care of the urinary bladder by tidal drainage, through a suprapubic cystostomy with cystometric readings, leading to the development of an automatic bladder. There is an excellent section on the care of decubitus ulcer both by sliding grafts and by whole thickness grafts taken from the posterior aspect of the thigh.

Disabling mass reflexes are seen with gross spasticity. As this prevents adequate nursing and the use of splints for walking, the treatment is shown to consist of anterior spinal root section from the eleventh thoracic to the fifth lumbar on both sides. The operation shows the identification of the first lumbar root by making use of the last tooth of the dentate ligament, which orients the operator. The result is completely flaccid lower limbs, which makes it possible to handle the patient much more easily with regard both to occupational therapy and to subsequent ambulation with braces.

Occupational therapy and morale building are stressed. Everything is done to make the patient personally independent. He is taught to develop power in his arms in order to move himself from bed to chair, and he is taught to care for his bladder. Finally he is taught useful things through which he may eventually earn a living. Stenographic work and radio making and repairing are among these. Finally the patients are taught to walk and to maintain ordinary everyday social contacts.

The emphasis is on technical equipment and mechanical aids, which are in abundance. Little is said about medication or the care of urinary tract infections. The mechanical removal of fecal material from the bowel is shown, but nothing is said about regulating the bowel. The section on the diet may be a little precious, but this may be excused by the necessity of attempting to estimate the number of calories the sick patient receives. The laminectomy for anterior rhizotomy shows the procedure fairly well, though it could be more carefully performed.

These are, however, only minor shortcomings, for the film is of great instructional value to all those unfamiliar with what is now routine treatment for paraplegics in the armed forces. The coordination of the numerous necessary facilities is a stupendous task which has been beautifully accomplished. It is to be hoped that some day civilian patients will have an opportunity to profit from a similar civil setup. The expense would certainly be justified, as this splendid motion picture clearly shows. Medical practitioners, students and specialists will be interested in what can now be done with patients they formerly regarded as almost hopeless. The photography is excellent.

Neurosurgery in an Overseas General Hospital. 16 mm., color, sound, 2,000 feet (1 reel), showing time fifty-five minutes. Produced in 1946 by the Medical Department, U. S. Army. Procurable on loan from Office of the Surgeon General U. S. Army, Pentagon Building, Washington, D. C. Attention: Chief of the Division of Education and Training.

Common army neurosurgical problems are set forth in a film that is divided into three sections dealing with peripheral nerves, penetrating head wounds and spinal cord injuries by missiles. Much of the first part, dealing with the care of the patient, is excellent. The color photography, especially of the operative fields, is poor; details are often scarcely discernible. The difficulty of obtaining detail is not always the fault of the photography, for the surgical field seems always to be covered with a thin layer of coagulating blood. The only means of keeping the wound dry appears to require suction. The ordinary use of gauze sponges would keep the wound cleaner and bring out more detail.

The peripheral nerve section is good and shows carefully planned preoperative and postoperative tests and exercises. The lesions demonstrated involve all the major nerve trunks. The operative technic as photographed leaves something to be desired, but the principles are sound. Tantalum cuffs are shown inserted round all sutures. This is optional and is contraindicated near joints, as the tantalum tends to work out of position. The section on penetrating wounds of the head is relatively short and demonstrates the removal of foreign bodies and tantalum cranioplasty. These are secondary operations, primary sutures and débridement having been carried out elsewhere. The encephalograms shown reproduced rather poorly. Brain abscesses, except in acute cases, are removed in toto; this is not demonstrated, but patients are shown after operation. In 1 case a large subcortical clot is removed. In the case with multiple indriven bone fragments, only one large fragment is removed under the eye of the camera and postoperative x-ray check is not demonstrated. The method of locating a metallic fragment by means of appropriate markings on the skull is shown. The section on spinal cord injuries concerns two typical gunshot wounds, one of the cauda equina and one in the midthoracic region. There is a quick view of the patients before operation on their air mattresses and with their tidal drainage. Nothing is said or shown concerning the infinite care of the skin and urinary tract nor the postoperative results, except to state that some of the patients came to walk with mechanical aids. The operations are both open to the technical objections already stated.

This would be a useful teaching film for medical students and would give some idea of the complexities of the problems which have to be faced. They would become aware of the fact that surgical procedure is only one in a series of steps involving the care of the patient. The film is rather long and when presented in its entirety presents more of a swift bird's eye view rather than anything that can be held and assimilated. It would probably be most useful divided and shown separately in its three principal sections of peripheral nerves, penetrating head wounds and gunshot wounds of the spinal cord.

The Story of Menstruation. 16 mm., color, sound, 400 feet (1 reel), showing time ten minutes. Produced in 1946 by Walt Disney Studios. Procurable on loan from International Cellucotton Products Company, 919 North Michigan Avenue, Chicago.

This excellent film is intended for showing to groups of adolescent girls in the 14-18 year age range to explain the physiology of menstruation with some practical corollaries.

It has long been a problem in schools how to present any material related to the reproductive processes without creating an atmosphere of tension, not to say fear and disgust. As one feminine member of a school board remarked, "I wish it were possible to present sex to girls in such a way that they would not thereafter associate the whole subject with old bewhiskered doctors threatening venereal disease."

This film is an answer to the problem; it accomplishes the extraordinary feat of teaching something essentially serious while preserving an air of good cheer and relieving the tension by unexpected humor. It consists entirely of animation, beautifully colored and accompanied by carefully worded commentary; it begins by indicating the manner in which the pituitary gland governs first the growth of the body and later the function of the ovaries. Next it shows ovulation and the passage of the unfertilized ovum. The thickening and the subsequent menstrual shedding of the endometrium is shown, and this is followed by suggestions as to bathing, diet, exercise and other hygienic measures in relation to menstruation. The film does not undertake too much, since it is specifically adapted to a particular group.

The introduction of this film into the schools should of course be accompanied by the teacher's guide and by the pamphlets for individual distribution.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, *March 29, page 964.*

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 24-26. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arkansas: * *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Written.* San Francisco, July 7-10. *Oral.* San Francisco, May 10-11. *Oral Clinical Examination for Foreign Medical Graduates.* San Francisco, June 21. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Delaware: *Examination.* Dover, July 8-10. *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia: * *Reciprocity.* Washington, June 9. Sec., Commission on Licensure, Dr. George C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: * Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

Hawaii: *Examination.* Honolulu, July 14-17. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Kentucky: Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maryland: *Medical Examination.* Baltimore, June 17-20. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Michigan: * *Examination.* Detroit, June 16-18. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota: * Minneapolis, April 15-17. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

Mississippi: Jackson, June 23-24. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Missouri: *Examination.* St. Louis, May 26-28 and June 9-11. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Building, Jefferson City.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

Nevada: *Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, April 7-8. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, June 23-26. Sec., Dr. Jacob L. Lochner Jr., State Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, May 1, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, June 17-20. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Endorsement.* Portland, April 25-26. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, June 23-25. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Texas: Austin, June 5-7 (tentative). Sec., Dr. T. J. Crowe, 918-20 Texas Bank Building, Dallas 2.

Vermont: *Examination.* Burlington, April 10-11. Sec., Dr. F. J. Lawliss, Richford.

Virginia: Richmond, June 18-21. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., Roanoke.

Washington: * Seattle, April 14-16. Sec., Miss Virginia Wotherspoon, Department of Licenses, Olympia.

Wyoming: *Examination.* Cheyenne, June 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: June 17. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: Little Rock, May 7. Sec., Mr. L. E. Gebauer, 701 Main Street, Little Rock.

Colorado: Denver, June 4-5. Sec., Dr. Esther B. Starks, 1459 Ogden Street, Denver.

District of Columbia: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: May 31. Final date for filing application is May 16. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

Iowa: Des Moines, April 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: Ann Arbor and Detroit, May 9-10. Sec., Miss Eloise Lebeau, 101 N. Walnut St., Lansing.

Nebraska: Omaha, May 6-7. Dir., Bureau of Examining Boards, State Department of Health, Mr. O. F. Humble, 1009 State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, May 4. Sec., Miss Marion M. Rhea, 114 E. March St., Santa Fe.

Oregon: June 7. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: *Examination.* Providence, May 14. Chief, Division of Professional Regulation, 366 State Office Bldg., Providence.

South Dakota: Vermillion, June 6-7. Sec., Dr. G. M. Evans, Yankton.

Washington: Seattle, April 8-9. Sec., Miss Virginia Wotherspoon, Department of Licenses, Olympia.

Wisconsin: Madison, April 12. Sec., Dr. William H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Court Not Bound by Preponderance of Expert Testimony.—The plaintiff was convicted of committing a lewd and lascivious act and of being a sexual pervert, from which judgments he appealed to the district court of appeal, second district, division 2, California.

Pursuant to the sexual psychopath provisions of the welfare and institutions code, the trial court appointed three physicians to examine the defendant and make their reports in writing. Two of them expressed the opinion that the defendant was a sexual psychopath; the third thought he was a sexual pervert. The defendant contended that this evidence did not support the finding that he was a sexual pervert. The court of appeals said that the trial court was not bound by a preponderance of the professional opinion but, on examination of the facts stated in the several reports, was at liberty to reach its own conclusions and to make its rulings in accord with the opinion of one of the physicians. The judgment of conviction was accordingly affirmed.—*People v. Parrish, 172 P. (2d) 89 (Calif., 1946).*

Insanity: Necessity for Evidence in Addition to Medical Certificate.—The petitioner was adjudged insane by order of the probate court and committed to the Veterans Administration Facility at Fort Custer, Michigan. From the order of commitment he appealed to the Supreme Court of Michigan.

It was the petitioner's contention that no competent evidence was produced at the hearing to prove his alleged insanity and that therefore the commitment was absolutely void. The probate judge based his findings on the testimony of the petitioner's wife (the only witness) and the certificates of two physicians. After examining the wife's testimony very carefully, the Supreme Court said that it did not prove insanity. We are mindful, the Supreme Court continued, that the probate judge also had before him the certificates of two duly appointed physicians, each of whom certified that petitioner was an insane person. Doubtless the probate judge relied mainly, if not wholly, on such certificates. But, concluded the court, it is settled law that an adjudication of insanity may not be based solely on the certificates of physicians appointed by the court to examine the alleged insane person. Accordingly the Supreme Court held that the order of commitment was void and that the petitioner was entitled to be discharged. —*In Re Haines, 24 N. W. (2d) 526 (Mich., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Value of Plasma Pitocinase Determinations in Obstetrics. E. W. Page.—p. 1014.
Cyclic Changes in Physical and Chemical Properties of Cervical Mucus. W. T. Pommerenke.—p. 1023.
Graphic Portrayal of Relative Pelvic Size. W. F. Mengert and W. C. Eller.—p. 1032.
Time for Postpartum Sterilization: Report of 150 Cases; Bacteriologic Studies on Postpartum Uterus. F. E. Whitacre, with assistance of W. M. Loeb Jr. and Laura Loeb.—p. 1041.

Rh Isoimmunization.—Philpott and his associates reviewed the records of 12,114 deliveries at the Royal Victoria Montreal Maternity Hospital for cases of erythroblastosis, severe jaundice of the newborn, severe anemia of the newborn, hydrops, hemolytic anemia of the newborn or any other diagnosis which might have been classified under hemolytic disease of the newborn. A total of 37 cases was found, of which 30 could be verified either by the demonstration of Rh antibodies in the mothers or on the basis of the presence in the same case of a combination of several other diagnostic points. Observations on surviving livebirths proved the great importance of repeated blood transfusions. Seven of the 30 pregnancies were interrupted at about the thirty-sixth week for the purpose of lessening damage to the fetus, but only 1 living child resulted from these 7 interrupted pregnancies. The present attitude in the Royal Victoria Maternity Hospital is that all obstetric patients are typed with standard Rh_0 agglutinating serum. When a woman is Rh negative, an attempt is made to determine her husband's type. If indicated, Rh negative women are tested for antibodies at the third, sixth and eighth months of pregnancy. If antibodies are present in the pregnant woman, the type and titer are determined; the titration is repeated each month. Increase of the antibody titer to a level of 1:100 is indicative of fetal involvement.

Thrombophlebitis and Phlebothrombosis in Gynecologic Patients.—The material for this report by Meigs and Ingersoll comes from the Massachusetts General Hospital. Tables show the number of patients operated on each year, the number of veins interrupted and the deaths from massive pulmonary emboli. The types of operations which preceded the vein interruptions are listed, as is the number of patients having presumptive evidence of pulmonary emboli. All surgeons at this hospital are convinced that interruption of the femoral veins is essential after a sublethal embolus or infarct. Nearly all are agreed that interruption of the femoral veins is essential after the diagnosis of thrombophlebitis or phlebothrombosis has been definitely made. The danger to the patient from interruption of veins is minimal and the operation is life saving.

Necrotizing Renal Papillitis.—Robbins and his associates discuss the clinical and pathologic aspects of the observations at necropsy in 26 cases of necrotizing papillitis of the renal pyramids, 19 of which occurred in diabetic and the remainder in nondiabetic persons. This lesion is a frequent type of acute pyelonephritis in diabetic patients. Clinically the cases divide themselves into a "fulminating" and a "subacute" group. In the former the presenting syndrome was one of sudden onset of severe systemic infection, often without localizing signs. The "subacute" cases usually presented obvious acute pyelonephritis for weeks to months until, without apparent prodromal symptoms, the urinary tract infection became much severer and the course assumed the character of the "fulminating" cases. Most of the deaths resulted from rapidly progressing uremia—8 in the diabetic group and all 7 in the nondiabetic. Some of the former, however, showed little renal insufficiency and death resulted from overwhelming infections. The pathogenesis is unrelated to any specific bacteria. It probably represents a severe type of inflammatory renal disease to which the diabetic patient and the patient with urinary tract obstruction are peculiarly susceptible.

Death Following Exposure to DDT.—Hill and Damiani report the death of a previously healthy man aged 47 twenty-five days after exposure to DDT. The symptoms began within twenty-four hours after exposure. The disease picture, both *clinically and at biopsy, simulated that of periarteritis nodosa*, and it is assumed that DDT possesses allergenic properties and should be included among other drugs that are believed to be capable of producing such a sensitizing reaction.

Streptomycin Therapy in United States Army Hospitals.—The clinical investigation reviewed by DeBakey and Pulaski was carried out at thirty general hospitals. In the 706 cases of infections of various kinds, streptomycin was administered parenterally, locally, orally or in combination, depending on the type of infection. Systemic administration of streptomycin maintained therapeutically effective levels in blood and urine. Intrathecal and intrapleural administration proved essential for infections involving the meninges and pleura respectively. In enteric infections the drug must be given orally. In most infections the combined route of administration was found essential. Topical use of streptomycin has not been attended with strikingly beneficial results. In urinary tract infections the successful use of streptomycin depends on a normal flow of urine. Recurrent urinary tract obstruction, urinary retention and undrained or unsterilizable foci, including the prostate, predisposed to relapse or reinfection. Treatment under these circumstances produced drug fastness. Streptomycin appears useful in gonococcic urethritis, especially in cases which prove resistant to penicillin and sulfadiazine. In wound infections streptomycin is effective only as an adjunct to surgery. In enteric infections caused by streptomycin susceptible organisms, the results of treatment are likely to be impressive. In bacteremia highly impressive results were obtained, but eradication of the focus by surgery is essential to success. Experience in tuberculosis was limited, but results justify further studies. In typhoid, streptomycin would seem highly effective in the acute state. In tularemia, streptomycin appeared to be the most effective chemotherapeutic agent. Vestibular disturbance was the only serious complication to streptomycin therapy.

Blood Loss in Operations.—The objective of this investigation by Baronofsky and his associates was to make a comparison of blood loss as measured by the gravimetric method and the loss as computed from the acid-hematin technic. Blood loss data have been assembled for representative surgical procedures. It was found that gravimetric determination of gain in sponge weight provides a reliable estimate of blood loss in surgical procedures. During appendectomy, blood loss averaged 25.8 cc. Hernia and gallbladder procedures averaged 82.9 and 179.4 cc. respectively. Comparison of the data obtained from subtotal gastrectomy for ulcer and carcinoma (499.8 and 455.6 cc. respectively) shows an unimportant difference. Thyroidectomy entailed an average blood loss of 405.6 cc., diffusely enlarged goiters providing most of the bleeding. The average loss during radical mastectomy was 415.4 cc. The average for pneumonectomy and lobectomy was 1,399 cc.

Primary Torsion of the Omentum.—Primary torsion implies the absence of any recognizable etiologic factor such as hernia, neoplasm, adhesive bands or inflammatory processes, while torsion in the presence of any such pathologic process is classified as secondary. The present report is concerned with the primary type of omental torsion, a lesion much less common than the secondary type. Within the past year the authors have operated in 3 cases of gangrene of the omentum caused by unexplained torsion and have found 3 similar cases in the records of the Cincinnati General Hospital during the last twelve years. These 6 cases, and a seventh reported by Andrus in 1926, constitute the largest group observed in any single clinic. The cause of the condition is obscure, but adiposity and strenuous physical activity apparently are predisposing factors. The condition is usually confused with acute appendicitis but should be suspected in obese or robust persons complaining of pain of several days' duration in the right lower quadrant of the abdomen, beginning during strenuous physical activity and being unassociated with vomiting. The treatment of choice is excision of the gangrenous portion of the omentum with ligation of the vessels of its pedicle. The prognosis is excellent.

Interpretation of Qualitative and Quantitative Serologic Reports. E. M. Holmes Jr. and Elsie P. Foxhall.—p. 28.

Trench Mouth, Scurvy and Vitamin C.—Schnurman maintains that the fusospirochetes are present in normal mouths as well as in trench mouth, so that a positive gingival smear alone is not sufficient evidence for making a diagnosis of trench mouth. If the vitamin C excretion in a twenty-four hour urine specimen is less than 13 mg., a positive gingival smear is of utmost diagnostic significance. As the result of deficiency in vitamin C an anaerobic state is created in the tissues and at the same time intercellular cement substance breaks down, allowing a port of entry to otherwise harmless saprophytes into an ideal medium where they become pathogenic. The author presents a technic for the rapid determination of vitamin C levels in body fluids and shows that patients with trench mouth who have low vitamin C diets improve without any other treatment than large doses of vitamin C.

Acute Appendicitis in the Aged.—According to Simpson from 1 to 2 per cent of attacks of acute appendicitis occur in patients over 60 years of age. The symptomatology differs considerably from the usual pattern in younger patients, but nevertheless there is a fairly well defined syndrome in the aged. Pain is often poorly localized, though nearly always present, and becomes intense only when peritonitis has supervened. The general reactions of nausea, vomiting, fever and elevated pulse rate are not found, though a slight fever is recorded in some cases. The localizing signs of rigidity, tenderness and pain on rectal examination are vague and inconclusive or are absent. Thus in the early stages the patient does not appear ill. Hence many cases are not seen until peritonitis has developed. Gangrene, perforation and peritonitis develop rapidly. In this advanced stage the condition may be confused with intestinal obstruction, and time may be lost in attempts to locate a growth. The author discusses the therapy (1) when there is a confident preoperative diagnosis, (2) when acute appendicitis is merely suspected and (3) when acute appendicitis is not diagnosed before operation. An illustrative case at the advanced age of 85, with survival, is reported.

Myasthenia Gravis and Pregnancy (Case Report). G. S. Adam.—p. 557.

South African Negro or Bantu as a Parturient.—Heyns and Shippel made an analysis of deliveries in 1,433 Bantu and 5,059 European women. A highly significant statistical difference for operative delivery was found, which shows that the European requires assistance at delivery more often than the Bantu. Maternal and fetal mortality were low in both series. Other features concerning parturition were analyzed, and it has been proved that the Bantu in her own home is a more efficient parturient than the European woman.

Relation Between Epilepsy and Pregnancy.—Following a review of the literature on epilepsy that complicates pregnancy, labor, the puerperium or lactation, Burnett says that at the West Middlesex Hospital during the seven years 1939 to 1945 inclusive there have occurred 21 deliveries in 18 epileptic mothers. Records of 19 of these pregnancies in 16 patients have been available for analysis. In only 1 case was there a family history of epilepsy. Four cases of menstrual epilepsy were encountered, of which 3 became worse during pregnancy. There were 2 cases of gestational epilepsy, 1 of which began in the pregnancy under review and 1 which began in a previous pregnancy. There was a total of 8 cases in which epilepsy became worse during pregnancy. In 6 cases 1 or more signs of preeclamptic toxemia were present. There were no fits during labor and none began during the puerperium. All infants were alive and healthy with the exception of 1 stillbirth. Breast feeding was allowed in 14 of the 18 cases and it never aggravated the epilepsy. However, breast fed babies tended to be sleepy if the mother received a sedative mixture containing bromides. The author presents 1 case of status epilepticus that occurred during pregnancy and in which termination of pregnancy was successful. He advocates interruption as the method of choice in such cases.

Psychosomatic Medicine. H. Hécaen and H. Duchène.—p. 730.

Importance of Sex of Donors and of Recipients in Blood Transfusions.—Hustin and Rémy report 80 reactions (9.2 per cent) in 864 blood transfusions given to 425 men and 439 women at a blood transfusion center in Brussels during 1942. The incidence of reactions was 5.3 per cent for cases in which both donor and recipient were men and 17.3 per cent in those in which both donor and recipient were women. The reactions were more severe if the donor was a woman, and particularly if the recipient also was a woman. The ratio of reactions was 7.2 per cent if the donors were only men and 7.7 per cent if the donors and the recipients were of different sex. The difference of 0.5 per cent does not warrant the exclusion of women as blood donors, but crossing of sexes is suggested for blood transfusions.

Globin Zinc Insulin. R. Boulin and Piérard.—p. 2029.

Sequels of Hypoglycemia.—According to Boulin hypoglycemia may be followed by retinal hemorrhages, by severe cardiac insufficiency or by myocardiac infarction and particularly by nervous disorders of various types, such as hemiplegia, epileptic attacks and idiocy. These irreversible manifestations are related to a great variety of lesions such as edema or hemorrhage. There is no consensus with regard to their pathogenesis; the majority of the authors believe that some type of asphyxia of the nervous centers is responsible. The symptoms of hypoglycemia are frequently confused with those due to coma of acidosis. The consequent administration of supplementary massive doses of insulin aggravates the hypoglycemia. Intravenous injection of hypertonic glucose solution, calcium gluconate and vitamin B_1 is the treatment of choice.

Silicosis and Hematogenous Tuberculosis.—Pathologic anatomic studies on 8 patients revealed to Zollinger that the association of silicosis with tuberculosis produces the anatomic conditions for increased passage of tubercle bacilli into the blood. The small pulmonary arteries and veins undergo some destructive inflammation and are thus deprived of their elastic tissue, an important defensive element against the tuberculous invasion. Silicosis produces many more contacts between tuberculous foci and the vessels than tuberculosis alone. In this way the tendency to hematogenous spread in the combination of tuberculosis and silicosis is explained. Furthermore, the destruction of lymph nodes by silicotic granulation tissue transfers tubercle bacilli into the blood directly as well as through the thoracic duct. The vascular damage due to silicosis plays a predominant part in the hematogenous dissemination.

Transplanted Cancer of Liver. L. S. Morozenskaya.—p. 152.

Cytotoxic Factor in Blood of Cancer Patients.—Roskin and Nastyukova demonstrated toxicity of the blood of patients with malignant tumors as well as of animals with induced tumors. The method employed was based on sensitivity of the paramecium to the toxic factors in the blood of cancer patients. The toxic effect which manifested itself in the destruction or in delayed division of the paramecium depended on two factors: one, specific cytotoxic factor and another which was apparently identical with the complement. Roskin attempts to demonstrate the specific toxicity of the serum of cancer patients. He hopes that clinical tests on a wider scale will give more information as to the species specificity of the toxic factor, the early toxicity in the blood of cancer patients and the prognostic value after irradiation or operation as well as the nature of the factor.

Cancerolytic Substance of Schizotrypanum Cruzi.—Klyueva and Roskin found that when mice with transplanted adenocarcinoma are infected with the South American trypanosome Schizotrypanum cruzi, the causative agent of Chagas' disease, it is possible to obtain cures in 70 per cent and a slower rate of tumor development in the remainder. This inhibitory action of Schizotrypanum is not limited to adenocarcinoma of mice but with less clearness may be shown for Crocker sarcoma, cancers 63 for the rat cancer of Flexner-Jobling. In normal animals the Schizotrypanums at certain stages of the infection gather in internal organs; in cancer animals the organisms gather in the tumor, that is, there is a tumor tropism phenomenon. The Schizotrypanums invade the malignant cells, in which degenerative changes may soon be noted, beginning with destruction of the nucleus and gradually the dissolution of the cell.

Hygiea

Congenital Cystic Fibrosis of Pancreas. K. Kaijser and C. W. Lundquist.—p. 2361.

Roentgenologic Determination of Size of Heart.—Denstad compared measurement of the size of the heart by Groedel's lung-heart quotient and the heart volume per square meter of body surface according to Jonsell's modification of Rohrer-Kahlstorf's formula in 377 adult patients (152 men, 225 women), 45 men and 60 women having no cardiocirculatory disturbances. He asserts that as a rule beginning enlargement of the heart is not demonstrable by either of these methods. Volume determination affords a more accurate expression of the size of the heart than the quotient. The heart is smaller in women than in men and also in relation to the breadth of the thorax and the body surface. In series determinations both methods are satisfactory, but here also volume determination gives a better picture of volume changes. In double determination caution is called for in drawing conclusions as to true changes in the size of the heart, especially in case of smaller deviations. Despite its important place in cardiologic diagnosis, x-ray determination of the size of the heart should supplement clinical evaluation.

Book Notices

An Integrated Practice of Medicine: A Complete General Practice of Medicine from Differential Diagnosis by Presenting Symptoms to Specific Management of the Patient. By Harold Thomas Hyman, M.D. Volumes I-IV, and Index. Cloth. Price, $50 per set. Pp. 1,032; 1033-2010; 2011-3095; 3097-4131; 4133-4336, with 1,184 illustrations and 310 Differential Diagnostic Tables. W. B. Saunders Co., W. Washington Sq., Philadelphia 5, 1946-1947.

The ultimate aim of the author was the production of an integrated practice of medicine written to meet the requirements of the general practitioner. This attempt to correlate the great advances made in the various specialties to the immediate problem of the patient in order to enable the practicing physician to view his patient not as a complex of isolated systems but as an integrated individual is most commendable. The recent progress in psychosomatic medicine has been concerned with this emphasis on the integration of the entire organism. More and more the necessity for a broader knowledge of all the specialties becomes apparent. The general practitioner should be able to serve competently from 60 to 80 per cent of the patients who consult him; the rest may require additional consultation. In the former group a variety of symptoms and diseases may tax the ingenuity of the practitioner to the utmost. Consequently a ready reference library is essential, and for that purpose these books are admirably suited and can be recommended.

Volume I is divided into six sections, on the general reactions of bodily tissues, infections, allergy, neoplasms, metabolism and poisoning. An admirable attempt is made in the first section to review briefly the basic principles of histology, cellular physiology and biochemistry, pathology and pathologic physiology. Unfortunately the author hurries into a series of tables on the differential diagnosis of hypopyrexia and hyperpyrexia instead of carrying to completion, in a somewhat more detailed fashion, his plan of refreshing the practitioner with a renewal of acquaintanceship on some of the more important aspects of the basic sciences as related to tissue physiology and pathology.

The section on infections is introduced by a short review of bacteriology, serology, immunology and nursing care of the infectious patient. Chemotherapy and antibiotics are discussed along with the older anti-infective agents before the specific infectious diseases are described. Infectious diseases are arranged and discussed in the familiar textbook fashion, but the attempt to tabulate all information which can be put into tables and to include in the discussion of each disease a multitudinous array of scientific facts sometimes leads to confusion. One reads of the pneumococcus and its characteristics, modes of invasion, sensitivity to serums, sulfonamides and penicillin but is abruptly startled to find himself confronted by advice to refer to such and such a page in volume III for a discussion of lobar pneumonia. Admitting the difficulties in organizing a complete practice of general medicine in a single textbook of four volumes, the multiplication of tables and numerous instructions to refer to other pages envisages the weary physician thumbing through a chain of page references one after the other to complete his picture of a single disease process. In general, the information on infectious diseases is adequate and current with rather more space devoted to laboratory data than to facts of value in bedside examination and diagnosis. Color plates of exanthems, microscopic slides and primary lesions are excellent.

The tabulated treatment schedules for syphilis should prove valuable. Eighteen pages are devoted to allergy and of necessity include only a superficial discussion of the subject. However, other manifestations of allergic responses are discussed in sections where the particular shock organ involved would naturally place them. The section on neoplasms is little more than a brief discussion of pathology and modes of treatment and could well be omitted, since the various tumors are described in the discussion of the disease processes in each body system in other sections of the text. The section on metabolism is divided into four chapters, on an introduction to the study of metabolism and nutrition, which includes a brief, concise description of metabolism of the major food components, minerals and vitamins; the American diet; practical dietotherapy; differential diagnosis, and the management of the common disorders of metabolism. The information presented is sufficient to meet the needs of the practitioner. The section on the circulatory system completes volume I. It begins with the basic physiology of the cardiovascular system and covers the functional and organic disturbances encountered in practice. A chapter on electrocardiography with eighty representative tracings is included. Tables of normal and abnormal variations are given. Unfortunately, except for an expert, this chapter is quite confusing and would not enable the practitioner to interpret his own tracings, yet one gains the impression that this was intended in this chapter. On the whole, this entire section is complete and concise and contains frequent personal opinions of the author which he has found successful in practice. This is a welcome departure from the usual textbook type of presentation.

Volume II consists of sections on the blood, endocrine, eye, nervous and digestive systems. The chapters on psychiatry and neurology have been written in a clear and concise manner and adequately meet the needs of the practitioner. In the discussion of hematologic conditions, the tables were found to be of great help in understanding the many variations. The chapter on the eye was found to be adequate for the purposes of the general practitioner. In the chapter on endocrinology there are some assertions which are open to criticism. For instance, on page 1254 it is stated that a glucose tolerance is mandatory if the fasting blood sugar is below 200 mg. Repeated high fasting blood sugar levels may be as diagnostic as a glucose tolerance test. On page 1250 the normal fasting blood sugar levels are given to be 120-150 mg. per hundred cubic centimeters. These are higher than the generally accepted levels in use today. It is also stated that a low basal metabolic rate is an indication for thyroid medication. A low basal metabolic rate may actually be misleading, especially in the management of obesity, since the test is calculated on the basis of actual and not ideal weight. Also the use of thyroid when diabetes is present can be quite hazardous.

Volume III consists of sections dealing with the respiratory, urinary, reproductive, skeletal and locomotor systems as well as obstetrics and pediatrics. The same general procedure is followed throughout with the frequent use of tables and cross references. On the whole, the descriptions of the various disease entities are accurate and the space devoted is commensurate with the relative importance and frequency of the disease. The atypical pneumonias, in particular, are adequately discussed. The superiority of frequent chest roentgenograms over the routine physical examination for the detection of early subclinical tuberculosis is not sufficiently emphasized. By the time signs of activity appear the process can no longer be considered "early" tuberculosis. In particular, the diuretics are well covered and completely presented.

Volume IV consists of sections on the tegumentary system, physical diagnosis, laboratory methods, therapeutics, pharmacotherapy, major and minor surgery, prognosis and an appendix. The section dealing with the integument covers 366 pages and contains many tables of differential diagnosis plus a sizable number of excellent colored plates. Many uncommon and, in fact, extremely rare conditions even in a dermatologic practice are discussed at some length. The author has devoted too much space to a discussion of these cutaneous disorders, and too much emphasis is placed on the infrequently occurring diseases. Here again some of the diagnostic tables tend to be confusing. In contrast to the other sections, the chapter dealing with the history and physical diagnosis seems unnecessarily elementary and superfluous in a work of this kind. The section dealing with laboratory methods includes technical considerations as well as normal and abnormal findings and the respective conditions in which the latter occur. Approximately 160 pages are devoted to medical therapeutics, which includes psychotherapy, physical therapy and drug therapy. This is followed by a section in which minor and major surgical procedures are discussed. There is a short section in which prognostic factors are considered. Finally, the appendix includes chapters on such subjects as establishing an office practice, glossary of hematology, occupational hazards and rehabilitation and convalescent care.

These volumes do accomplish the avowed purpose of the author; they will prove to be of distinct value to the general practitioner who desires a readily accessible and compact review of the various branches of medicine. Sufficient information is given in a manner that will enable the practitioner to evaluate more adequately the problems presented by his patients and to become more expert in the methods of diagnosis.

Hygiene: A Textbook for College Students on Physical and Mental Health from Personal and Public Aspects. By Florence L. Meredith, B.Sc., M.D., Professor of Hygiene and Public Health, Tufts College, Boston. Fourth edition. Cloth. Price, $4. Pp. 838, with 155 illustrations. Blakiston Company, 1012 Walnut St., Philadelphia 5, 1946.

This is a complete revision of a widely used and valuable textbook on college hygiene. In the preface the author states as the theme which runs through the book "what health situations exist in the lives of individuals and peoples, what health objectives arise from them, and what action is scientifically appropriate on the part of the layman, especially the college student." With this theme in mind the author presents the usual material on personal and public health in a manner which should arouse the interest of college students in their own health problems and motivate them to seek a solution of such problems. In this edition not only has there been a revision to bring statistical and other material up to date but there has been a complete rearrangement of much of the material. The six parts and forty-nine chapters in the previous edition have been rearranged and expanded into nine parts with fifty-seven chapters. New chapters have been written to give emphasis to some of the major health problems such as heart disease, cancer, rheumatism and allergic conditions. An enlarged and much improved chapter on heredity has been included. Many of the anatomic and other illustrations have been redone in a manner which greatly improves the illustrative material. This is unlike most textbooks on college hygiene in that Dr. Meredith does not separate the discussion of the various aspects of health into personal and public as such but rather combines the personal and public health aspects of all topics as they are discussed. This approach has much to recommend it. One criticism which may be made of this as of former editions is its length. Many instructors feel that a textbook of 800 pages is too long for class use. In some instances also it seems that the detailed anatomic descriptions and terminology are too complex for the average college student and could have been simplified to good advantage. The great improvements which have been made in the revision should make this textbook used even more widely than in the past. It can be recommended for use by college students and others interested in the general field of health.

Textbook of Biochemistry. By Benjamin Harrow, Ph.D., Professor of Chemistry, City College, College of the City of New York, New York. Fourth edition. Cloth. Price, $4.25. Pp. 592, with 144 illustrations. W. B. Saunders Company, W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, 1946.

As the rapid and extensive advances in biologic chemistry necessitate frequent revisions and editions of a textbook in this field, the new edition is highly welcomed. Much of the newer knowledge has been incorporated. Treatment is given to such newer topics as transamination, transmethylation, thiouracil in hyperthyroidism, alloxan diabetes and the antibiotics. No mention, however, is made of the interesting spreading phenomenon which involves hyaluronic acid and the enzyme hyaluronidase. Immunochemistry is inadequately treated. These topics will no doubt receive adequate consideration in the next edition. An appendix has been added; it deals with a variety of topics many of which could have been better discussed in their proper place in the text.

The claim is set forth that more clinical material has been added throughout the book. These additions nevertheless are too meager to be considered a great improvement over the third edition. It is to be hopd that more clinical material will be found in the fifth edition. It is taken for granted that each successive edition is an improvement over the last edition. In this respect Harrow's book has shown consistent improvement.

The paucity of clinical integrations and correlations is not to be taken as adverse criticism: it holds for all the textbooks in biochemistry at present available. Our textbooks in this field seem to be written with an eye to the capturing of the greater buying market which embraces students of agriculture, sanitary engineering, nutrition, dietetics, dentistry and pharmacy, and advanced students in general chemistry or biology. Unless the teaching of biochemistry is permeated with medical implications, as is the teaching of physiology, pharmacology and especially bacteriology and pathology, the subject will continue to stand alone and apart in the medical curriculum. Because of this isolation it yet remains a subject which medical students look on with no too great a show of kindness and as an academic drudgery in which a passing grade must be attained in order to advance from one class into another.

The references at the end of each chapter are excellent. These make a specialty of reviews rather than of individual original papers. Since students carrying a full academic load as a rule are crowded for time and have little opportunity for outside reading, the text could be materially improved by incorporating more of the highlights of these reviews.

The book has many good points to recommend it. The chapters on vitamins and hormones cover the subject well and are interestingly illustrated by pictures of animals and of human beings displaying signs of vitamin deficiency or hormonal inadequacy or excess. Excellent are the chapters dealing with the intermediate metabolism of carbohydrates, fats, lipids and proteins and the chapters dealing with biologic oxidations and biologic detoxications.

The new edition can be profitably placed in the hands of students of medicine and of physicians who wish to keep abreast of the times in the ever expanding field of biochemistry and who wish to make their own integrations between medicine and biochemistry. It is to be remembered that the newer knowledge in the latter field often parallels advances made in the fundamental understanding of the cause of disease and in the application of proper therapeutic procedures.

The Psychology of Adolescence. By Karl C. Garrison, Associate Professor of Education and Psychology, Teachers College of Connecticut, New Britain. Third edition. Cloth. Price, $4.65. Pp. 355, with 22 illustrations. Prentice-Hall, Inc., 70 5th Ave., New York 11, 1946.

This is written primarily for college students, parents and teachers. It is also a textbook for students of adolescent behavior, in which text is supplemented by comprehensive bibliographies. An introductory section defining adolescence and classifying briefly the problems of this age period is followed by a section dealing with physical and mental development, emotional growth and adolescent attitudes and interests. Detailed discussion of personality development during adolescence and adaptation at home, in the school and in the community is presented. Social and sexual development are thoughtfully, if briefly, considered. A final section is directed to guidance of adolescents. Here physical and mental hygiene principles and the prevention of delinquency and of educational and vocational needs are summarized. It is a well written book in which there has been careful selection of the material presented. It can be profitably read by parents, by teachers and by adolescents. It deals with the primarily socially determined problems of behavior, although the author fully recognizes the important biological factors in adolescent behavior and the crucial significance of childhood relationships and training. As a work on the mental hygiene of adolescence it is excellent. The counselor who must deal with the individual adolescent who presents problems reflecting deviations in personality development will require more specific understanding of psychodynamics than are offered in this textbook. The extensive bibliographies are meager in reference to the technical and clinical works in which childhood and adolescent behavior are thus dynamically interpreted.

A Guide for the Tuberculous Patient. By G. S. Erwin, M.D., Medical Superintendent, Liverpool Sanatorium, Frodsham, Cheshire. American edition revised and edited by Henry C. Sweany, M.D., Medical Director of Research, Municipal Tuberculosis Sanatorium, Chicago. Paper. Price, $1.50. Pp. 126. Grune & Stratton, 381 4th Ave., New York 16, 1946.

In both the preface and the introduction the authors call attention to the importance of information on tuberculosis to the patient. This can best be provided by a small volume written with as few scientific words as possible so it can be easily read by patients, regardless of previous education and training. This volume is a fine example of such an accomplishment. The authors have long been in the field of tuberculosis and are highly respected by the medical profession for their store of information and fine judgment. There are ten chapters on such subjects as the cause of tuberculosis, diagnosis, complications, treatment, public health aspects and nonpulmonary tuberculous lesions. The patient is told practically everything that he needs to know in order to cooperate to his best advantage with professional workers. Because of differences in such factors as the prevalence of tuberculosis in various parts of the world or even in the same country, it is impossible to make statements concerning phases of the disease that are applicable everywhere. For example, the assertion that primary infection usually occurs in childhood, while applicable to many nations, does not apply to vast areas of the United States, where far more infections occur among adults than among children because of the low infection attack rate and the many more years devoted to adult life than to childhood. In addition to discussions of the fundamentals of tuberculosis, the authors have manifested excellent judgment in the presentation of subjects of special current interest, such as mass surveys, vaccination, aviation, life insurance, tuberculosis and childbearing, and streptomycin. Every physician who treats tuberculosis will find this book of distinct value to his patients.

Pasteur. By Henri Mondor. Paper. Price, 150 francs. Pp. 189, with illustrations. Éditions Corrêa & Cie, 166 Boulevard du Montparnasse, Paris, 1945.

The physician interested in Pasteur may wish to include this recent biography in his collection, though it offers little that is new. The well known facts of his life have been presented in much more interesting manner by other biographers. The personal history, the human side of Pasteur, the significance of family and religious and academic training are hardly touched on. Only the dogged persistence of Pasteur in the face of apparent failure and painful rebuke is emphasized, as well it should be, for it was the basis of Pasteur's ultimate success. Pasteur was not an unusually good student; he was by no means a genius in the usual implication of sudden flashes of inspiration and intuitive penetration of dark fields. Pasteur's great contributions follow a clearly defined and logical course of reasoning in an orderly steplike fashion, and each step was carefully built up by hard work and tenacious adherence to a mental pattern. Pasteur was a far greater man than the rather colorless figure that Henri Mondor has presented to us in this book.

Oral Diagnosis and Treatment: A Textbook for Students and Practitioners of Dentistry and Medicine. By Samuel Charles Miller, D.D.S., F.A.C.D., Associate Professor in Charge of the Periodontia Department, New York University College of Dentistry, New York, and Thirty Contributors. With an introduction by Allen T. Newman, M.S., D.D.S. Second edition. Fabrikoid. Price, $10. Pp. 903, with 613 illustrations. Blakiston Company, 1012 Walnut St., Philadelphia 5, 1946.

This is a book of unusual value and interest to both practitioners and students of medicine and dentistry. Few physicians realize the number of serious systemic conditions that have their first clinical manifestations in the oral cavity, for instance measles, scarlet fever, diabetes, blood dyscrasias, including pernicious anemia, metallic poisoning and many of the occupational diseases. The thirty contributors have been selected because of their ability to present the material of their respective chapters. The material in each chapter is so arranged as to make it easily available for reference. Each chapter is supplied with a bibliography and suggested reading.

The chapters of special interest to the physician and medical student are chapter 1, on the science of oral diagnosis, by Samuel Charles Miller, D.D.S.; chapter 2, on head pain, by R. J. Behan, M.D., assisted by B. J. Johnston Jr., M.D.; chapter 3, on pain of dental origin, by John Oppie McCall, D.D.S.; chapter 6, on diseases of the oral mucous membranes exclusive of neoplasms, by George M. MacKee, M.D., and Anthony C. Cipollaro, M.D.; chapter 20, on tumors of the oral mucous membrane, by George M. MacKee, M.D., and Anthony C. Cipollaro, M.D.; chapter 21, on mouth infections and their relation to systemic disease, by Harold Stearns Vaughan, M.D., D.D.S., and Louis R. Burman, Ph.G., D.D.S., and chapter 24, on oral manifestation of endocrine dysfunctions, by William Wolf, Ph.D., M.D. Of special interest at this time are the chapters on oral and dental diseases of occupational origin, by J. A. Salzmann, D.D.S., and on acrodontia (aviation dentistry), by Lieut. Col. James M. Mullen, D.D.S., Dental Corps, Army of the United States.

The book deserves a place in the reference library of every physician and dentist who is called in consultation.

Practical Malariology. Prepared under the Auspices of the Division of Medical Sciences of the National Research Council by Paul F. Russell, M.D., M.P.H., Colonel, M. C., A. U. S., Parasitology Division, the Army Medical School, Luther S. West, Ph.D., Head of Biology Department, Northern Michigan College of Education, Marquette, Michigan, and Reginald D. Manwell, Sc.D., Professor of Zoology, Syracuse University, New York. Foreword by Raymond B. Fosdick, President of The Rockefeller Foundation. Cloth. Price, $8. Pp. 684, with 238 illustrations. W. B. Saunders Company, W. Washington Sq., Philadelphia 5; 7 Grape St. Shaftesbury Ave., London W. C. 2, 1946.

Dr. Russell had a distinguished career as field director in malaria for the Rockefeller Foundation before he became head of the malaria section of the Office of the Surgeon General of the United States Army during the recent war. While in the Army, Dr. Russell served for a time as chief malariologist for the American forces in North Africa and Italy. Thus his experience in malaria control has been unusually extensive.

As stated in the preface, the subject matter of the volume has been derived mainly from the experience of the authors. Their aim has been to provide information of a practical nature for day to day use in the clinic or in the field. Having appeared after the war, the book is designed primarily for civilian rather than for military use. The restrictions which were imposed during the war have since been relaxed, so that it has been possible for the authors to discuss all the important new developments in malariology.

The text is divided into six sections, on the parasite, the mosquito, the man, the community, prophylaxis and control, and therapeutic malaria. An appendix contains an extensive key to Anophelines of the world, useful tables of equivalents and a voluminous index.

The historical introduction stimulates interest and provides perspective. The sections dealing with the parasite present known facts clearly, simply and systematically. A valuable feature of these sections is that gaps in knowledge which need to be filled are pointed out.

The colored illustrations of plasmodia are excellent. Their value is increased by the numbered documentation which explains them and which is made possible without injuring the plate by the use of transparent interleaves. Some of the halftones in these sections have a blurred appearance.

The section on laboratory and field technic is informative and useful. Recent work on the cultivation of malaria parasites is described. Some of the information contained in the sections which deal with the taxonomy, life cycles and bionomics of malaria transmitting mosquitoes has been presented in convenient tabular form. The halftones and diagrams of this section are excellent. The symptomatology and the treatment of malaria are succinctly and clearly presented. The epidemiology and the methods of controlling malaria are dealt with in extenso. It is especially on these aspects of malariology that Dr. Russell's experience qualifies him to speak with authority. The sections are well illustrated with halftones and diagrams.

Although presented by the authors in the modest guise of a practical manual, this volume is also an excellent book of reference. The subject matter throughout is presented clearly and concisely, and the approach is scholarly.

Operative Surgery. By George Bankoff, M.D., D.Ch., F.R.F.P.S. Fabrikoid. Price, £3 3s. Pp. 416, with 479 illustrations. Medical Publications, Ltd. 47 Princes Gate, London, S. W. 7, 1946.

This ambitious little book attempts to cover almost all the fields of surgery. In this wise it is a typical product of the English, who are given to publish handbooks, some of which are excellent. Few surgeons in this country would feel that a work of this nature would prove of value either for teaching or for advanced study. Typically much of it is anatomic, and little space is devoted to physiology, indications or complications. The illustrations are excellent and numerous. Descriptions of technics are limited but concise and well expressed. There is much common sense in its content. This volume can be of use as a basis for a review of surgery.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF AMEBIASIS

To the Editor:—What is the present practice in the United States in regard to (1) treatment of patients with dysentery or other symptoms of amebiasis, (2) treatment of amebiasis during pregnancy, (3) treatment of persons passing cysts but without symptoms or other evidence of ill health and (4) the isolation of patients and disposal of excreta?

R. I. MacDonald, M.D., Toronto, Ont.

ANSWER.—1. The drugs considered to be most useful in the treatment of amebiasis include chiniofon, diodoquin, vioform, carbarsone and emetine hydrochloride. The treatment usually recommended varies, depending on a number of conditions such as the severity of the symptoms, the general condition and age of the patient and previous treatment. In adults with acute amebic dysentery or amebiasis causing severe diarrhea, one course of emetine hydrochloride followed by one or more courses of chiniofon is commonly recommended. Patients with definite but less severe symptoms may be treated with one of the amebicidal drugs other than emetine hydrochloride. Chiniofon or diodoquin is perhaps the most frequently recommended for this purpose.

A course of emetine hydrochloride consists of 0.065 Gm. (1 grain of the drug) given subcutaneously or intramuscularly once a day for seven to ten days. The patient is kept at bed rest throughout the period of emetine administration. A course of chiniofon consists of 1 Gm. of the drug by mouth three to four times daily for eight to ten days, and this is usually repeated after one to two weeks. Additional courses of chiniofon may be given if evidence of amebic infection persists, or courses of diodoquin or carbarsone may be substituted. Modifications of this routine are indicated in certain cases, depending on the response, both therapeutic and toxic. Toxic symptoms due to emetine in adults are uncommon when (1) the patient is at bed rest, (2) the total dose of emetine hydrochloride administered in one course is 0.780 Gm. (12 grains) or less and (3) the course is not repeated before six months. Toxic symptoms due to chiniofon are not serious. Diarrhea or an exacerbation of diarrhea occurs commonly, but this is not severe usually and promptly subsides when the drug is discontinued on completion of the course.

2. One of the iodine-containing amebicidal drugs such as chiniofon or diodoquin is considered the treatment of choice. The use of emetine hydrochloride during pregnancy is discouraged. In fact, it is considered by some to be contraindicated. It is not definitely known that emetine has an unfavorable effect on the fetus or that it favors abortion, but that it might have such an effect seems likely in view of the fact that emetine is a known protoplasmic poison. It would therefore be difficult to justify the use of emetine hydrochloride during pregnancy should an abortion follow, even though the abortion might well have been a spontaneous one. In a pregnant woman seriously ill with amebic dysentery who fails to respond to other drugs, the benefits anticipated from emetine hydrochloride might seem to outweigh the risks sufficiently to warrant its use. Such cases, however, must be rare.

3. Chiniofon, vioform and diodoquin are frequently used in the treatment of asymptomatic amebiasis. Chiniofon may be used in courses as outlined. Vioform 0.25 Gm. taken by mouth three times daily for ten days constitutes one course, which may be repeated after one to two weeks. The recommended dose of diodoquin is two to three tablets of 0.21 Gm. (3⅕ grains) each three times daily for twenty days. Carbarsone also may be used. Although it is less toxic than other amebicidal arsenicals, severe toxic reactions have occurred, and for this reason it is not the drug of choice for the first course of therapy.

4. Hospitalized patients, by law in most states, are isolated and the stools disposed of as in cases of typhoid. On the other hand, most patients with amebiasis are probably ambulatory during treatment. In the latter event the patient is not permitted to engage in occupations involving the handling of food for public consumption. This, of course, does not prevent him from handling food consumed by his family or friends. It then becomes the function of the physician to instruct the patient concerning personal hygienic measures.

MANNITOL HEXANITRATE FOR HYPERTENSION

To the Editor:—Please discuss the use of mannitol hexanitrate in the treatment of hypertension.

M.D., Connecticut.

ANSWER.—Mannitol hexanitrate is a useful drug in the management of hypertensive disease. It is a vasodilator belonging chemically to the series of alkyl nitrates, which includes glyceryl trinitrate and erythroltetranitrate, but pharmacologically to the group of nitrites which includes sodium nitrite and amyl nitrite. Mannitol hexanitrate has a more prolonged effect than either of the other two alkyl nitrates; the arterial tone remains reduced for five or six hours.

Continued administration of any or all of the alkyl nitrates leads to increasing tolerance. Tolerance to glyceryl trinitrate is acquired quickly. Abstention from the drug for a few days usually restores responsiveness. Apparently the nitrites act directly on the arteriolar musculature. The nitrite ion is extraordinarily unstable. The normal concentration of nitrite ions in the blood stream is about 1 microgram per hundred cubic centimeters of blood. This is increased to 2 or 3 micrograms by all the alkyl nitrates and by sodium nitrite, amyl nitrite and bismuth subnitrate. However, one peculiarity which remains unexplained is the great variability in effectiveness of the various compounds. Approximately the same degree of fall in arterial tension follows the administration of 1 mg. of glyceryl trinitrate, 40 mg. of erythrol tetranitrate, 50 mg. of sodium nitrite or 100 mg. of amyl nitrite. These differences are not *explained by differences in NO_2 ion content.*

The usefulness of vasodilator drugs in hypertensive disease is limited by several factors. In the later phases of the disorder, when considerable arteriolar sclerosis exists, they are nearly valueless and may be detrimental. In hypertensive states due to arteriolar hypertonicity prior to the sclerotic changes they are most valuable when no active vasopressor influences are operative and the hypertension is largely due to the intrinsic self-perpetuating character of the malady. The degree of arteriolar relaxability of the arterioles in any given case of hypertension may be quickly determined by the amyl nitrite test (Stieglitz, E. J.: Evaluation of the Prognosis in Arterial Hypertension, *Arch. Int. Med.* **46**:227 [Aug.] 1930). The response of the blood pressure to amyl nitrite is an excellent guide to what may be expected from any of the several vasodilators mentioned.

Toxic reactions from the alkyl nitrates are rare, though about 25 per cent of hypertensive patients exhibit poor tolerance and complain of headache for an hour or two after ingestion of these drugs. Sometimes tolerance is acquired by persisting in the treatment despite the cephalalgia but it is wiser to reduce the dosage and then increase it very slowly. The nitrates are distinctly safer and less toxic than potassium thiocyanate.

TRANSMISSION OF BRUCELLA IN MILK

To the Editor:—The county agricultural agents and the veterinarians quote Dr. Huddleson as stating that undulant fever is transmitted only by direct contact with Bang's infected cattle or meat and not by drinking the infected cow's milk. In support of this statement they point to the lack of any cases of undulant fever that cannot be traced to such contacts despite the large consumption of raw milk from these cows. In my epidemiologic investigation of over 20 cases in this area I have found this to be true. However, I am in accord with most physicians who hold a contrary view. Has Brucella abortus been isolated from milk? Have experimental animals contracted the disease after ingesting such milk? Is pasteurized milk with a plate count of 100,000 per cubic centimeter considered as safe as raw milk with a count of 10,000 or less? In other words, is pasteurized milk free from all pathogenic bacteria regardless of the size of the plate count?

M.D., Michigan.

ANSWER.—The veterinarians and county agents are apparently misquoting Dr. Huddleson. In the 1943 edition of Huddleson's "Brucellosis in Man and Animals," pages 71-73, the discussion of ports of entry of Brucella in relation to occupation, varieties of the micro-organism and reported regional experiences is followed by this statement: "In our opinion it seems probable that in general the greater number of human infections are acquired through the ingestion of the organism."

Brucella abortus has been isolated frequently from milk. Several well documented milk borne outbreaks of human brucellosis caused by the porcine variety are illustrative of the nonoccupational mode of transmission to man of the less virulent and epidemiologically less explosive bovine variety (Beattie, C. P., and Rice, R. M.: Undulant Fever Due to Brucella of the Porcine Type, THE JOURNAL, May 19, 1934, p. 1670. Horning, B. G.: Outbreak of Undulant Fever Due to Brucella Suis, *ibid.*, Dec. 14, 1935, p. 1978).

From the point of view of protection against brucellosis, pasteurized milk with a high plate count is safer than any raw milk. Brucella organisms are readily killed by pasteurization.

CONGENITAL MEGACOLON

To the Editor:—What is the expectancy for a patient aged 17 years with a known diagnosis for six years of Hirschsprung's disease? At present the disease is under reasonable control. Also I would appreciate, if available, a suggestion as to the present regimen, surgical and medical, for this syndrome. In my practice it seems that I have seen only 1 instance in patients other than children.
M.D., Michigan.

Answer.—The frequency of congenital megacolon (Hirschsprung's disease) seems to be inversally proportional to the age of an individual. Its most common occurrence is among children, and usually the child has sought medical aid before he reaches the second decade of life. A few, however, have little or no objective complaints except abdominal enlargement and can go on to the middle years of life without much of any trouble. People with advanced megacolon after the age of 40, seemingly in good health, have been encountered. This is exceptional.

The advisability of medical or surgical treatment in these cases will rest largely on the state of advancement of the megacolon. In the mild or moderate cases anticonstipation programs together with the use of drugs affecting the sympathetic and parasympathetic nervous systems have helped. In some of these and the somewhat more advanced cases in children, sympathectomy has been performed with variable results. The treatment of choice seems to be subtotal colectomy.

POSSIBLE SUBACUTE COMBINED DEGENERATION

To the Editor:—A diagnosis of subacute combined sclerosis was established one year ago in a man aged 68 on the basis of a history of tingling and numbness in the hands, neurologic findings, a low red cell count not typical of pernicious anemia, and an achlorhydria. He was given liver extract, reticulogen 1 cc. weekly, diluted hydrochloric acid twenty drops with meals, and a vitamin B complex capsule. On this therapy he improved. At the present time, however, he complains of generalized weakness and loss of strength. The patient weighs 129 pounds (58.5 Kg., no change in several years), his height is 5 feet 7 inches (170 cm.), he appears healthy, his tongue is pale and smooth with tortuous venules on the under surface and petechial-like spotting of the mucous membrane, there is a systolic heart murmur, the blood pressure is 160/90, the liver edge is palpable two fingerbreadths below the costal margin and not tender, there is a loss of biceps, triceps, patellar and achilles tendon reflexes, the abdominal reflexes are questionable, the cremasteric reflexes are active, there is atrophy of the small muscles of both hands, fibrillary twitching has existed in the hands for three years, vibratory sense is reduced, heat, pain and touch sensation is normal, the patient is unable to distinguish small objects placed in the hands, he experiences difficulty in executing the finer movements of the hands, there is loss of position sense of the toes and he has a tendency to drag the left foot in walking. Laboratory examination reveals the urine normal, creatinine excretion 0.978 Gm. in twenty-four hours, erythrocytes 4,750,000 (same counts since 1940), hemoglobin 90 Gm. per hundred cubic centimeters (Sahli), color index 0.92, reticulocytes 0, megaloblasts 0, leukocytes 9,100, of which polymorphonuclears were 62 per cent, stabs 4 per cent, lymphocytes 32 per cent, monocytes 3 per cent and eosinophils 3 per cent, sedimentation rate (Wintrobe) 0, Price-Jones curve single peak average 7.3 microns. Marrow studies were not made. Blood and spinal fluid serologic reactions for syphilis were negative, spinal fluid Pandy test was negative, colloidal gold curve was 2233221111. Diagnoses of atypical pernicious anemia and progressive muscular atrophy have been considered. Evidence against syphilis includes lack of history or scar of primary lesion, normal pupils and negative serologic tests. Please discuss the diagnosis and treatment. Is the increased tortuosity of the venules on the under surface of the tongue common? Does folic acid influence neurologic changes in typical pernicious anemia?
M.D., California.

Answer.—The neurologic findings of the patient described in the query are not typical of the subacute combined degeneration associated with pernicious anemia. Against this diagnosis are the weakness of one foot, the loss of the biceps and triceps reflexes, the presence of astereognosis and the abnormal colloidal gold curve. Atrophy of the small muscles of the hand and fibrillary twitching are not unusual in old age in the absence of neurologic disease. A definite neurologic diagnosis cannot be made from the findings described.

Achlorhydria is not diagnostic, as this occurs in more than 20 per cent of persons in this age group. Tortuosity of the venules under the tongue is common and has no relation to pernicious anemia.

It is stated that the red cell count was low one year before. A rapid response of the count to parenteral treatment with liver would favor the diagnosis of pernicious anemia. Knowledge of the course of neurologic symptoms and signs during liver therapy would also be helpful. In pernicious anemia the neural symptoms would either improve or remain stationary; they should not progress. As this diagnosis cannot be excluded, parenteral liver therapy should be continued. Fifteen units every two weeks should be adequate.

Preliminary observations indicate that the neurologic changes in some cases of pernicious anemia are not controlled by folic acid.

REMOVAL OF CALCIUM

To the Editor:—Is there any method to reduce the calcium content of the body?
Charles C. Morrison, M.D., Bar Harbor, Maine.

Answer.—It is presumed that the inquiry refers to a reduction in the calcium content of body fluids. A second possibility would be the reduction of the calcium content of soft tissues that have become calcified.

Hypercalcemia most commonly results from the ingestion of large amounts of vitamin D, from hyperparathyroidism, from the rapid destruction of bone as by a lytic bone tumor, or from the immobilization of a part of the skeleton. In the first instance, stopping the ingestion of the hypercalcemic sterol, placing the patient on a diet low in calcium and maintaining a high water intake will lead to a decrease in serum calcium. This decrease may be rapid and striking if the patient has been on a high calcium intake, as is frequently the case. In hyperparathyroidism, reducing the intake of calcium may cause a slight reduction in serum calcium although no decided effect will result unless the hyperfunctioning tissue is removed. The administration of soluble phosphates has been suggested as a means of lowering the serum calcium in hypercalcemia. This procedure seems unwise, as it may contribute to metastatic calcification and the impairment of kidney function. A return of weight bearing to the formerly immobilized part of the skeleton will result in a return of the serum calcium to normal.

Reducing the calcium content of soft tissues is frequently impossible if the deposits occur in the presence of a normal calcium content of the body fluids. If the calcification of soft tissue occurs in the presence of hypercalcemia, spontaneous mobilization of the soft tissue deposits is likely to occur when the underlying cause of the hypercalcemia has been removed (Freeman, Rhoads and Yeager: Toxic Manifestations Associated with Prolonged Ertron Ingestion, The Journal, Jan. 26, 1946, p. 197. Danowski, Winkler and Peters: *Ann. Int. Med.* **23**:22 [July] 1945). Parathyroid, citrates and various acidifying salts such as ammonium chloride will mobilize calcium from the skeleton, but their effect is on the skeleton as a whole without regard to any particular locality. These measures would have little if any effect on deposits of calcium in the soft tissues.

Theoretically it should be possible to hasten the rate of reduction of an elevated serum calcium by the oral administration of unabsorbable substances that would combine with the calcium of food and with the calcium contained in the gastrointestinal secretions. Actually, no substance suitable for this purpose has yet been demonstrated.

RECURRENT ERYSIPELAS

To the Editor:—A patient aged 56 years has had erysipelas eight times in the last two years. The attacks occur on either the left or the right lower part of the leg. The acute stage responds readily to the sulfonamides and to penicillin. What can I do to prevent the frequent recurrences?
Harry Grodzicker, M.D., Brooklyn.

Answer.—Since erysipelas is a disease of the skin and mucous membranes due to hemolytic streptococci, it is assumed that in the case cited this micro-organism has been identified as the etiologic agent. If not, attempts should be made to isolate the organisms from the tissues or blood during an acute attack. There are two possibilities to explain the recurrent attacks. Repeated episodes of erysipelas have been explained on the basis of an allergic reaction, that is, the presence of tissue which is hypersensitive to a product or products of the hemolytic streptococcus. During the acute attack the inflamed tissues usually do not contain viable organisms, but the causative factor is some distant focus or foci harboring hemolytic streptocicci. Therefore, in the case under discussion it would be well to search for a focus such as a chronic sinusitis. Eradication of the primary focus is essential for the prevention of recurrent attacks, and this may necessitate surgical intervention. Desensitization with the hemolytic streptococcus, using either a vaccine or exotoxin prepared from the organisms, has been unsuccessful. A second possibility for explaining the genesis of the attacks is the presence of chronic lymphedema of the legs with localizing of micro-organisms in the tissues. The edema may be associated with varicose veins, chronic congestive heart failure, obesity and, finally, thrombophlebitis. Congestion of the legs associated with inflammation and infection leads to more fibrosis of the tissues and an increase in the lymphedema. Such a sequence of events is probably present in filariasis, where it is known that hemolytic streptococci may localize in the tissues of the legs. In the case under discussion, recurrent attacks of thrombophlebitis should be seriously considered. If this is the cause of the repeated attacks, treatment may require surgical ligation of the veins; or anticoagulant therapy with heparin, the administration of penicillin and vasodilation with local heat over a period of three to four weeks may be utilized.

DOSAGE SCHEDULE FOR QUINIDINE

To the Editor:—What is the excretion rate of quinidine sulfate when employed in the usual dosage of 100 to 200 mg? It is my impression that the drug when so given (orally) is completely excreted within two to three hours, so that, in order to effect control of cardiac arrhythmia, a less frequent administration would be much less effective. The question is prompted by the prevailing custom, at my hospital, of ordering administration every four hours or three times a day. M.D., New York.

ANSWER.—The question of the optimal frequency of administration of quinidine has occasioned considerable discussion. Electrocardiographic studies during quinidine administration have thrown considerable light on the problem. Such studies indicate that the maximal effect of a single oral dose is obtained from one and one-half to three hours after administration and is maintained at a slightly lower degree for three to five hours following, which it decreases rather rapidly. Subsequent doses lead to a summation of effects; hence, if too large doses are given at too frequent intervals, cumulative poisoning may develop. These findings would indicate that in acute conditions the drug should be administered at one to two hour intervals until the maximal effect is developed. For chronic auricular fibrillation and in the prophylactic treatment of paroxysmal arrhythmias, the conventional four hour schedule should be adequate. The average dose is usually considered to be 200 to 400 mg. rather than 100 to 200 mg.

PROGRESSIVE BULBAR PALSY

To the Editor:—What, if any, specific therapy is there for the treatment of progressive bulbar palsy? Sidney A. Chait, M.D., Torrington, Conn.

ANSWER.—Progressive bulbar palsy is a rare disease in which the anterior horn cells of the bulb have degenerated. Death usually results in a period of six months to five years—mostly after two years. There is no known efficacious treatment. Rarely one sees a case that has all the manifestations of progressive bulbar palsy in which there occurs a period of arrest and the patient recovers. Every patient should have the benefit of the following treatment: 150 mg. of thiamine hydrochloride hypodermically three times a week for five weeks, 25 minims (1.5 cc.) of whole wheat germ oil three times daily for four weeks, atropine sulfate $\frac{1}{120}$ grain (0.54 mg.) for sialorrhea and a diet consisting of 50 per cent liquids of high caloric value.

NICOTINIC ACID FOR HEADACHE

To the Editor:—Please give the detailed technic of the intravenous injection of niacin for headache. S. Joe McKinsey, M.D., McAllen, Texas.

ANSWER.—Technics differ in the intravenous administration of niacin for headache. Atkinson, in the treatment of migraine, prescribes a course of injections followed by oral maintenance dosage, while Goldzieher and Popkin, in treating various types of headache, recommed the administration of 100 mg. of nicotinic acid or its equivalent as the sodium salt at the outset of each attack. The method recommended by Atkinson is as follows: First give an intramuscular injection of 25 to 35 mg. of nicotinic acid to determine by the extent of the flush reaction the individual tolerance of the patient. (It should be stated that many workers regard the flush reaction as valueless.) Estimating dosage from this reaction, Atkinson gives a series of six or eight intravenous injections, starting with 20 to 30 mg. and raising the dosage by daily increments of 5 mg. to a level of 50 mg. or such lower limit of tolerance as may supervene. After this course of intravenous injections the patient is taught to give himself intramuscular injections of 25 to 50 mg. at daily or thrice weekly intervals as indicated by symptoms or experience. At the same time tablets (50 to 150 mg. a day) are taken. Depending on the response to treatment, the patient is ". . . weaned from injections and kept on a maintenance dose by mouth."

ANTIHEMOPHILIC GLOBULIN

To the Editor:—A man aged 22 with hemophilia urgently needs a kidney operation. Is there a new antihemophiliac blood substance which will offer safety in surgery for such patients? What is the name of the product and is it available commercially?

D. D. McRoberts, M.D., Lewiston, Idaho.

ANSWER.—The substance referred to in the query has been isolated from normal blood plasma by workers at the Thorndike Memorial Laboratory of the Boston City Hospital (Lewis and others: *Blood* **1:** 166 [March] 1946). They term this substance "antihemophilic globulin." Single injections of 200 to 400 mg. will reduce the coagulation time of hemophiliac patients to low levels for eight to twelve hours. This work is in the experimental stage, and the material is not available commercially.

For the patient mentioned in the query, 125 to 250 cc. of whole blood or an equivalent amount of fresh plasma should reduce the coagulation time of the blood to almost normal for one to two days. Further blood or plasma may be given as indicated. For local hemostasis, a purified thrombin preparation or fibrin foam may be useful.

ERGONOVINE AND POSTERIOR PITUITARY INJECTION

To the Editor:—After delivery is it compatible to give ergotrate (ergonovine) and pituitrin (posterior pituitary injection) together in the same syringe or should these be given separately?

William F. Chamlee, M.D., Hanford, Calif.

ANSWER.—It is not advisable nor indicated therapeutically to administer ergonovine and posterior pituitary injection in the same syringe. When administered intramuscularly they both exhibit their action in six or seven minutes. Intravenously they take effect almost immediately, in thirty or forty seconds. The action of ergonovine lasts two to four hours, of posterior pituitary injection several minutes. Qualitative differences in the uterine motility are not induced by the two drugs administered intravenously. Therefore it is not necessary to use posterior pituitary injection if ergonovine is administered. In many thousands of patients in a large maternity hospital, ergonovine has proved to be the ideal oxytocic drug because of its uniform effectiveness and the complete absence of any undesirable symptoms.

RESTORATION OF DESTROYED NAIL BED

To the Editor:—Eighteen months ago a 28 year old man tore the right thumb nail about three quarters off. The nail has never grown fast to the anterior three quarters of the nail bed which I believe is replaced by scar tissue. I have considered removing most of the nail, scarifying and then making fairly wide linear incisions through the healthy nail bed forward to the end of the thumb in the hope that this may correct the defect. D. Guilford Dudley, M.D., Endicott, N. Y.

ANSWER.—It is probable that the nail bed was partially destroyed at the time of the original injury. Unfortunately no way is known of securing satisfactory restoration of a destroyed nail bed.

One cannot say dogmatically that the procedure suggested will fail, but there is no logical reason for believing that incisions through the scar will have any helpful effect.

DURATION OF SCROTAL HERNIA

To the Editor:—I have the problem of determining whether an indirect left scrotal hernia was acquired within a period of four months or prior to this period. Is there a method of determining the length of existence of this type of hernia? Angelo J. Gulino, M.D., Plainfield, Conn.

ANSWER.—An accurate method of determining, within a few days or a few weeks, the length of time an indirect scrotal hernia has been present has not been found, although at times the duration may be approximated with a fair degree of accuracy. One of the difficulties lies in the well known fact that some cases of indirect hernia are congenital in origin and may exist as a narrow peritoneal sac with a small neck in the inguinal canal or even in the scrotum for a long time before becoming manifest clinically as a bulging mass in the groin which is accentuated by coughing or straining and is reducible when lying down. This may develop so gradually and be accompanied by so little discomfort that the patient is scarcely conscious of its presence; or it may come on suddenly after a strain or heavy lifting and produce such severe pain that the exact date of its occurrence is easily remembered. In such an event it is fairly easy to determine the duration of the actual herniation. Fairly good evidence also may be gathered at the time of operation, because a thin walled sac might indicate a hernia of recent development, whereas if the sac is a large one and has thick walls and within its lumen one finds adherent omentum or adherent bowel it would speak strongly for a process of much longer duration.

THE MANAGEMENT OF JAUNDICED PATIENTS

Consideration of the Indications for Surgical Treatment

ALBERT M. SNELL, M.D.
Rochester, Minn.

Friedrich Theodor Frerichs,[1] whose "Clinical treatise on diseases of the liver" is one of the neglected classics of medicine, began his discussion of the management of jaundiced patients with the sentence: "In the treatment of jaundice the first point to be considered is the causes which have led to the accumulation of bilious matter in the blood." There is no panacea for jaundice and the first problem is, as it was in the time of Frerichs, that of ascertaining the pathologic mechanisms involved in the particular case.

While many excellent classifications of jaundice have been advanced, one which represents an oversimplification of the problem is best suited as an approach to the subject of therapeutics. It is that of McNee,[2] who regarded jaundice as hemolytic, hepatocellular or obstructive. The hemolytic varieties may be recognized by appropriate studies of the blood and of the products of breakdown of hemoglobin. Evidence of serious hepatic dysfunction is usually absent. For these reasons, such cases seldom present a major problem in differential diagnosis. The obstructive types may be identified by the signs and symptoms of interference with biliary flow, such as colic, intermittent or permanent acholia and retention in the blood of biliary constituents other than bilirubin. Considered in the mass, obstructive jaundice seldom presents serious evidence of disturbed hepatic function unless it is of long duration. Hepatocellular jaundice does not present, as a rule, any evidence of interference with biliary flow into the intestine, and, in contrast to the aforementioned types, it shows early and conclusive evidence of interference with the metabolic and other functions of the liver. It is on these diagnostic premises that a differentiation sufficient for therapeutic purposes may be made.

The most troublesome diagnostic problem is presented by the patient whose jaundice was initiated without severe pain. It is of particular importance to concentrate attention on this type of case today because of the worldwide dissemination of infectious hepatitis which has occurred during World War II, the frequently reported incidence of homologous serum jaundice subsequent to the use of blood and plasma and the apparently increased frequency of portal cirrhosis. These are distinctly medical disorders in which surgical treatment has no place, but unfortunately they may be confused clinically with the painless, obstructive variety of icterus due to tumors of the papilla of Vater and head of the pancreas, to the treatment of which the Whipple operation has been applied with such encouraging results.

A great many diagnostic short cuts have been suggested for the differentiation of obstructive and hepatocellular jaundice, most of which are based on the previously mentioned fact that gross disturbances of hepatic function occur early in the course of primary hepatic disease and late when there is obstruction of the extrahepatic biliary passages. The hepatic functional tests commonly used in this differentiation appear in the accompanying table. They constitute part of the "profile" study suggested by Watson and his associates[3] and, if used with an understanding of their limitations, are clinically valuable. However, any one whose experience with jaundiced patients has been at all extensive can recall many cases of both obstructive and intrahepatic jaundice in which the observations were at considerable variance with this table. One rather cynical observer has remarked that the greatest value of hepatic functional studies lies in the fact that the time required for their performance gives one the opportunity to take a complete history and to examine the patient. Perhaps it would be fairer to say that the tests are as good as the clinical abilities of the user.

In the doubtful case of painless obstructive jaundice the proof is in the demonstration of actual biliary obstruction. Of considerably more clinical importance, therefore, is the remaining portion of the "profile" series of tests, which include studies on urinary and fecal urobilinogen.[4] Data from these studies give reliable information in regard to the patency of biliary passages and, incidentally, will detect the presence of excessive hemolysis. Formerly clinicians depended to a considerable extent on the chemical analysis of the stools for bile pigment and on the use of duodenal intubation in the diagnosis of obstruction of the biliary passages. Positive results from these sources are reliable, but negative information is considerably less so. A bulky stool with a low bilirubin content will give a negative Schmidt test, and a negative result of examination of the duodenal contents for bile may be due to technical error in the location of the tube.

From the Division of Medicine, Mayo Clinic.

Read in a Symposium on "Treatment" before the Section on Experimental Medicine and Therapeutics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Stokes,[5] who is now studying the reliability of all methods for determining the existence of biliary obstruction, has permitted me to mention some of his preliminary studies. When no bile was obtained by duodenal drainage in his patients, the position of the tube was checked roentgenologically. In 78 per cent of cases the tube was found to be in the stomach rather than in the duodenum. Even when duodenal drainage did not produce bile, determinations of urobilinogen in the stools showed values above the range of complete obstruction in 53 per cent of the cases studied by him. In 5 instances in which there was absence of bile in the duodenum on drainage and roentgenologic examination showed the tube to be in the duodenum, the urobilinogen in the stool was above the range of malignant obstruction and, in fact, within the normal range in 4 of the 5 cases. In no instance was duodenal drainage positive for bile when the urobilinogen in the stool was in the range of complete obstruction.

These observations indicate clearly that the only physiologically satisfactory proof of complete biliary obstruction (which is, of course, the rule in occlusion of the biliary passages by malignant lesions) lies in the demonstration of exceedingly low levels of fecal and urinary urobilinogen. While such studies are tedious they seem definitely in order when one is considering a procedure of such magnitude as the Whipple operation for pancreatic cancer.

Results of Hepatic Functional Tests in Obstructive Jaundice and in Hepatocellular Jaundice

Test	Type of Jaundice	
	Obstructive	Hepatocellular
Plasma cholesterol	Elevated	Normal or low
Alkaline phosphatase	Increased	Normal
Serum protein	Normal	Reduced; reversed albumin-globulin ratio
Thymol turbidity	Negative	Positive
Cephalin-cholesterol flocculation test	Negative	Positive
Excretion of hippuric acid	Normal	Decreased
Effect of vitamin K on prothrombin time	Prompt	Delayed or absent

One may, then, recommend as necessary for diagnosis the battery of functional tests which constitute the "profile" series of Watson. They are not intended to substitute for clinical judgment, but their use definitely extends the range of diagnostic accuracy in the doubtful case; as a supplement to careful clinical study they leave little margin for error. In addition to their usefulness in the detection of complete biliary obstruction and hemolytic icterus they may give one assurance in advising an exploratory operation when there is equivocal clinical evidence of primary hepatic disease in patients suspected of having stone in the common duct.

SURGICAL INDICATIONS

Comments on surgical indications by one whose primary interest lies in the field of medicine may at first glance seem impertinent. These are offered only as opinions, which may well be challenged. Surgeons have at times been swayed by Moynihan's[6] dictum of an earlier epoch, that "no man living is infallible in the diagnosis of jaundice." They have accordingly been inclined to explore the biliary passages under circumstances which give little hope of benefit and which entail considerable risk. The surgeon can effect a cure only if there is mechanical interference with the extrahepatic flow of bile; no amount of external biliary drainage can reasonably be expected to improve hepatocellular damage. The surgical consultant ought, therefore, to insist on reasonable proof of mechanical biliary obstruction, partial, intermittent or complete, before undertaking the task of exploring the biliary passages of a jaundiced patient. Such proof depends not only on the presence of such familiar signs and symptoms as colic, a distended gallbladder, an external biliary fistula or complete acholia but on the assurance that any evidence of diminished hepatic function is minimal or at least consistent with the duration of the patient's jaundice. Hence, what I consider to be the indications for surgical treatment and the relative contraindications against it will be considered separately.

The following circumstances in connection with the presence of jaundice are considered to warrant surgical exploration of the biliary passages.

1. *A Reliable Past History of Gallstones or Colic or Both.*—The fact that the biliary passages have once been shown to contain stones is of the greatest significance. The patient whose former cholecystogram has shown multiple stones has a 13 to 20 per cent chance of having calculi in the duct also; with simple cholesterol stones or a roentgenologic diagnosis of a nonfunctioning gallbladder the probability of stones in the duct is considerably less. One should always recall that in spite of many warnings by surgical authorities the common bile duct is not explored as thoroughly or as often as it should be. Even if the ducts are free of calculi, inflammation or edema involving the gallbladder, ducts or pancreas may produce temporary jaundice in patients who have calculous cholecystitis. Hence, a previously positive cholecystogram or a history of removal of a stone-filled gallbladder, may be of great value in arriving at a decision.

It should be emphasized that jaundice due to stone may not be associated with colic; it may be unusual in its chronologic relation to the appearance of jaundice; pain, too, may be absent or atypical in character and location. If the gallbladder has previously been removed, the onset of icterus is more frequently associated with typical colicky seizures.

The story of colic in such cases should be carefully appraised and most conservatively interpreted; and one should not neglect to obtain firsthand information in regard to previous surgical treatment and roentgenologic studies. Above all, one need not under these circumstances be deterred from exploration by the absence or the atypical character of pain.

2. *Proved Intermittent Biliary Obstruction with Fever.*—Exploration in cases of proved intermittent biliary obstruction with fever is aimed primarily at the silent ball-valve stone, the symptomatology of which was so well described by Osler.[7] The rare benign tumors of bile ducts may produce a similar clinical syndrome; the same may be said of the equally uncommon primary stricture of the duct and of the more frequently encountered late postoperative stricture with incomplete obstruction of the duct. Chronic relapsing pancreatitis is another diagnostic stumbling block.

The principal diagnostic point in such cases is to be sure of one's facts, and it is expected that reasonable proof of intermittent acholia and of a "spiking" curve of serum bilirubin should be available. The greatest danger lies in the fact that patients who have chronic hepatitis, hepatic atrophy or cholangitis also may have intermittent icterus and fever. So far as possible, primary hepatic disease should, therefore, be excluded. If the liver is large, a needle biopsy may be a worth while preliminary procedure.

[7] Osler, W.: A Clinical Lecture on the Ball-Valve Gall-Stone in the Common Duct, Lancet **1**: 1319-1323 (May 15) 1897.

3. *An Associated Biliary Fistula With or Without Acholic Stools.*—The need for exploration in a case in which there is an associated biliary fistula with or without acholic stools requires no discussion; the great majority of cases are due either to postoperative stricture or to an overlooked stone in the common duct. The fistula may occasionally communicate with a subhepatic extra-ductal pocket of retained bile.

4. *Painless Jaundice Appearing Within Six Months After Cholecystectomy.*—As is generally known, in the majority of cases in which painless jaundice appears within sixty days after cholecystectomy it is due to traumatic stricture or even to accidental section of the common bile duct at operative intervention. Care must be taken to exclude homologous serum jaundice with its long incubation period of sixty to one hundred and twenty days. A negative Hanger test or the absence of thymol turbidity should give the surgeon assurance on this latter point.

5. *Proved Complete and Permanent Biliary Obstruction.*—The completeness of mechanical blockage of the bile duct due to carcinoma of the pancreas, papilla or common duct has been repeatedly emphasized. It is in this type of case that radical resection of the obstructing lesion has been performed with such gratifying results. The prime consideration here is the proof of complete occlusion, with permanent absence of bile in the stool. The corroborative value of determinations of urobilinogen in stool and urine has already been mentioned. Palpation of the distended gallbladder, now almost a lost art, is also of great diagnostic value. Both the surgeon and the patient should be prepared for a most extensive and dangerous surgical procedure. One can, as has been said, "settle for a cholecystogastrostomy," but in these times radical resection is the ultimate goal.

It is realized that these indications for exploration are conservative and that the surgeon may frequently and properly decide to proceed with operative intervention on much less definite grounds. He may, for example, be quite justified in exploring the ducts of a patient with chronic jaundice who shows minimal evidence of hepatic dysfunction, and he may be rewarded by finding a surgically removable lesion, such as stone. Whether the indications are clear or not, it is believed that the relative contraindications against surgical intervention should always be given consideration in making a decision. As will appear later, these danger signals are associated either with the presence of primary hepatocellular disease or with serious hepatic damage secondary to prolonged biliary obstruction. They may not necessarily interdict exploration, but they are always worthy of review in any given case.

RELATIVE CONTRAINDICATIONS TO SURGICAL TREATMENT OF JAUNDICED PATIENTS

1. *A Recent History of Exposure to Hepatotoxic Agents.*—A routine inquiry in regard to a recent exposure to hepatotoxic agents should be made in all cases of jaundice. It is well to recall that many patients having "toxic" hepatic injury may have abdominal pain and digestive disturbances at the onset. In these times the diagnostic possibility of epidemic infective hepatitis must also be considered. In such cases, the onset of symptoms is frequently characterized by fever and abdominal pain, and in more than one case the symptoms have been tentatively regarded as being due to calculous obstruction.

2. *Transfusions or Plasma Infusions Sixty to One Hundred Days Previously.*—The danger of confusing homologous serum jaundice due to transfusions or plasma infusions sixty to one hundred days previously with that due to other causes cannot be overemphasized, since the former condition has a significant mortality rate, much of which occurs during the first week or ten days after the appearance of jaundice. Some time should be allowed to elapse before a final decision is reached in the doubtful case.

3. *Vascular "Spiders"; Visible Collateral Circulation.*—Pulsating angiomas which appear in the distribution of the superior vena cava are almost the trademark of primary hepatic disease. They occur but seldom in patients with stricture. Visible distention of the abdominal veins has a similar significance, as it indicates interference with portal blood flow.

4. *Fetor Hepaticus.*—The peculiar odor of the breath associated with hepatic insufficiency does not lend itself well to descriptive terms. It has been described as sweetish, mousy or resembling the odor of certain aromatic amines. It is especially likely to occur in the later stages of hepatic atrophy or cirrhosis and can never be safely disregarded.

5. *Edema or Pronounced Hypoproteinemia or Both.*—These findings are rare in cases of obstructive jaundice and the presence of edema or pronounced hypoproteinemia or both should always serve as a warning to the surgeon who is considering exploration.

6. *Extrahepatic Tumor Masses.*—Masses in the right upper quadrant of the abdomen projecting from the inferior surface of the liver may be due to primary carcinoma of the gallbladder or they may be due to malignant lesions of the stomach or splenic flexure, with or without hepatic metastasis. In case of doubt, appropriate roentgenologic studies and visualization of the liver by the aid of thorium dioxide sol should be carried out. The latter procedure has a special field of usefulness if metastasis or primary hepatic cancer is suspected.

7. *Decidedly Chronic Jaundice with Splenomegaly.*—Patients presenting the syndrome of decidedly chronic jaundice with splenomegaly are usually suffering from what has been described as hypertrophic or pericholangiotic biliary cirrhosis. A few may present associated lipemia and xanthomas. Many show little evidence of interference with hepatic function even after long periods. As a group, these patients are seldom benefited by any surgical procedure.

8. *Intense Jaundice with Patent Biliary Passages.*—Patients whose bilirubin levels are in excess of 25 mg. per hundred cubic centimeters of serum are most frequently afflicted with primary hepatic disease (infectious hepatitis, atrophy or cirrhosis), primary carcinoma of the liver or extensive necrosis of the hepatic parenchyma secondary to biliary obstruction.[8] Even when there is good reason to believe that the biliary passages may have been previously occluded, the surgeon should proceed with great caution and consider the results of hepatic functional studies with unusual care.

---

[8] Snell, A. M.: Hepatic Parenchymal Lesions and Hepatic Function of Patients with Obstructive Jaundice, Tr. Am. Gastro-Enterol. A. 35: 196-225, 1932.

9. *Evidence of Active Hemolysis.*—It is rare for either hemolytic anemia or jaundice to simulate an obstructive lesion of the biliary passages, but it should be recalled that the association of gallstones and congenital hemolytic jaundice is a common one and that occasionally patients who have cirrhosis may also present evidence of hemolytic phenomena.

10. *Greatly Reduced Cholesterol Esters or Failure of Hippuric Acid Synthesis.*—A low or falling blood cholesterol level and a diminution of the cholesterol esters to less than 50 mg. per hundred cubic centimeters of plasma are indicative of severe parenchymal hepatic injury. Hippuric acid excretion of less than 50 per cent of normal has a similar significance and indicates an increased surgical risk.

11. *Hypoprothrombinemia Refractory to Vitamin K.*—No matter how complete or prolonged mechanical obstruction to the biliary passages may be, the prothrombin deficit which results is almost invariably responsive to the oral or parenteral administration of vitamin K. In primary hepatic disease the prothrombin deficit may not be as great, but it is usually completely refractory to treatment. The effects of vitamin K therapy may, therefore, be of diagnostic value[9] and are at times sufficient to establish the diagnosis of primary hepatocellular injury, as has been mentioned in the table.

As has been said previously, these contraindications are purely relative and may on occasion be disregarded. In general, however, the presence of one or several of them in the individual case should discourage any hasty surgical intervention.

It is regrettable that no specific precautions can be taken against one of the most unfortunate happenings in the field of biliary surgery; namely, exploration performed on patients with "compensated" cirrhosis. For reasons which are as yet unknown, these patients may present themselves with biliary colic, jaundice and other features of the syndrome of stone in the common duct. The mechanism of the pain and jaundice in such cases is obscure, but the signs and symptoms may be such that even the most experienced surgeons are misled. A high index of suspicion and a search for other signs of cirrhosis are about the only available safeguards.

DIETETIC AND OTHER TREATMENT OF JAUNDICED PATIENTS

Dietetic Considerations.—A consideration of the physiologic aspects of experimentally produced hepatic injury and of the principles on which current conceptions of treatment are based is beyond the scope of this paper. The protective value of a high carbohydrate intake is too well known to require discussion here; the need for an adequate protein intake is not so generally appreciated. The fear of using protein in the diet dates back to the early studies on dogs that had Eck fistulas and the experiments of Bollman[10] on the influence of meat extractives in producing ascites. It suffices to say that these studies do not necessarily apply to the clinical field. The interdiction of fat is based on the known need for bile in the intestine to facilitate its digestion and absorption, as well as on the observed vulnerability of experimental animals maintained on high fat diets to hepatotoxins. However, a low fat diet is an unpalatable affair at best, and the tendency for the past ten years has been toward liberality in this respect. The recent report of Rivers and Hoagland[11] indicates that, even in severe infectious hepatitis, a relatively high fat intake is without harmful effect. In fact, these workers noted that recovery of weight and strength is more rapid when such diets are used.

The clinical use of choline, methionine and similar lipotropic agents is based on studies of animals maintained on deficient diets. The application of these observations to the human subject is still under investigation. Clinical results have not so far been particularly encouraging. It may be that methionine may be found to have a specific field of usefulness as a "detoxicating" agent under certain conditions, and the drug also may spare endogenous lipotropic compounds.

The requirements for specific vitamins in the presence of jaundice are not known, except in the case of vitamin K. However, the clinical picture of hepatic insufficiency presents many of the aspects of a deficiency state, which in turn may be due to inadequate absorption of vitamins, to failure of their normal metabolism or to their actual destruction in the body of the affected person. It is on this rather insecure basis that the case for vitamin therapy rests.

The Treatment of Patients Who Have Obstructive Jaundice.—Management of patients with obstructive jaundice must be highly individualized. Many patients who show minimal disturbance of hepatic function require little or no special care, while others who have been jaundiced for a long period may have sustained serious hepatic injury, which will tax one's therapeutic resources. The diet should contain at least 350 Gm. of carbohydrate and 150 Gm. of protein daily; the intake of fat may be liberalized if it is tolerated by the patient. It is rather unusual to find a patient who cannot take at least 100 Gm. of fat a day. Dextrose need not be given intravenously except when the patient is vomiting or unable to eat. The advisability of its use during the immediate preoperative and postoperative period is, however, well established.[12] The intravenous use of protein hydrolysates is believed to be unnecessary except when the patient is malnourished. Transfusions need be used only as necessary to maintain a normal level of hemoglobin. Vitamin K should be given intravenously in dextrose solutions just before operative intervention or orally, together with bile salts to insure its absorption, for a few days before the operation, and its administration should be continued during the postoperative period to compensate for the fall in prothrombin which usually occurs. Other vitamin therapy should be given only on the basis of specific indications.

Postoperative care should include fluid administered parenterally (chiefly in the form of dextrose solutions) in sufficient quantities to maintain a positive fluid balance and a normal output of urine. In this connection it is well to follow the blood protein-nonprotein nitrogen level. If it is found to be elevated, the parenteral intake of fluid should obviously be increased, since renal insufficiency is still a common postoperative development. In occasional patients, especially those with stricture and long-standing jaundice, transfusions, plasma or serum albumin will be required to maintain the level of hemoglobin and plasma proteins during the postoperative state. A high carbohydrate, high protein diet of the type described previously, with vitamin supplements as needed, should be ordered for the convalescent patient, and every effort should be made to induce the patient to eat. In fact, an adequate diet before and after surgical operation is the only special care which many patients who have obstructive jaundice require.

Treatment in the Primary Hepatocellular Forms of Jaundice.—The management of the primary hepatocellular forms of jaundice has been gradually altered since the publication of Patek's[13] reports ten years ago and is now directed chiefly at the maintenance of an optimal nutritional state, with specific treatment for such deficiencies of vitamins and protein as may occur. The diet should contain 350 to 500 Gm. of carbohydrate, 100 to 150 Gm. of protein and 100 to 150 Gm. of fat. It is the usual practice to plan the diet with the idea of deriving a considerable portion of fat and protein from vegetable sources, eggs, dairy products, beef and liver. The diet may be liberalized considerably to suit the tastes of the person concerned. The major problem is not to prescribe a diet of particular composition but to insure the ingestion of a maximal amount of nutritious food. Since many of these patients have no desire to eat and even a profound disinclination to do so, the task of feeding them is a difficult one. The diet should be measured, if necessary, and the caloric intake charted. Supplementary infusions of dextrose and protein hydrolysates are often necessary to bring up the caloric intake and to maintain fluid balance. A normal level for hemoglobin should be insured by frequent transfusions of blood.

There is increasing evidence to indicate that one of the principal features of hepatic insufficiency is a failure to metabolize ingested protein. Many patients who have primary hepatic disease have, as is generally known, significant reductions in the serum albumin with or without a compensatory rise in globulin. Not a few have albumin levels of less than 3.5 Gm. per hundred cubic centimeters of serum, a point at which ascites and edema will usually occur. The hypoproteinemia in these cases should be vigorously treated and it has often been noted that [illegible] will run parallel to a rising serum albumin level. The amount of plasma and serum albumin required to affect serum protein levels is large. The necessary dose of plasma is usually 500 to 750 cc. two or three times a week,[14] until a normal blood protein level is reached and 250 to 500 cc. weekly thereafter to serve as a maintenance dose. Serum albumin should be given in initial doses of 50 to 100 Gm. daily, until the serum proteins reach a safe level. A maintenance dose of 25 to 50 Gm. every few days thereafter will usually suffice.

Recent studies at the Rockefeller Institute indicate that the use of extract of liver may enhance the beneficial effects of infused protein.[14] The Rockefeller workers, using a special preparation of liver designed for intravenous use, have, by gradually increasing the amounts injected, brought the dosage up to 10 cc. two or three times a week. The material is given diluted with isotonic solution of sodium chloride and does not often produce any reaction, even if its administration is continued over fairly long periods. Crude liver extracts also have had a beneficial effect, but their use is more likely to be attended by reactions than is that of the purified extract.

The use of such lipotropic substances as choline and methionine is now in the investigative stage, and there is some rather inconclusive evidence to indicate that they may be of therapeutic value. In a recently reported series of cases[15] of infectious hepatitis the use of these substances did not shorten the course of the disease, and a personal experience of mine with patients who had homologous serum jaundice appeared to be in line with these results. However, as Beams[16] has claimed, there is a reasonable basis for the use of these substances if the patient has a large and presumably fatty liver.

In an earlier paragraph it was stated that chronic hepatic insufficiency presents many of the features of a complex deficiency disease. On this basis it is now the usual practice to supplement the treatment mentioned previously with liberal quantities of vitamins. Some source of the vitamin B complex seems to be an essential part of treatment. If powdered brewers' yeast can be tolerated it may be given in doses up to 30 Gm. three times daily, diluted in tomato juice. Many patients object to its taste, and it is necessary to depend on the various proprietary preparations of the B complex in concentrated form. Thiamine chloride and nicotinic acid should be given in liberal amounts to patients who are receiving large quantities of dextrose intravenously. These portions of the B complex enter into the composition of enzyme systems essential to the metabolism of carbohydrate and may readily be exhausted if many vitamin-free calories are given. Thiamine and nicotinic acid also apparently have a place in the treatment of hepatic coma and the encephalopathic states, although they do not by any means constitute specific remedies for these conditions.

Ascorbic acid requirements may be met by the liberal use of orange juice, which increases the palatability of the diet. Vitamin D and extra calcium salts may be added to the diet of patients who show evidence of osteoporosis. Vitamin K is apparently not utilized in the presence of primary injury of the hepatc cells, although large doses may have some effect in keeping the blood prothrombin above a critical level.

I am not aware of any specific need for vitamin A, riboflavin, pyridoxine hydrochloride, pantothenic acid or folic acid (the Lactobacillus casei factor), although they may be employed if any specific indications for their use can be demonstrated.

A final word may be said in regard to the treatment of hepatic insufficiency. It is far easier to prevent than to treat and, once it appears, there seem to be no specific remedies available other than those described previously. These should be pushed vigorously in the hope of maintaining the best possible nutritional state for the patient and allowing time for some regeneration of hepatic tissue. Anoxemia, which may be a feature in some cases of hepatic failure, appears to depend on a qualitative alteration of hemoglobin.[17] The only means of treatment known to date are to supply normal hemoglobin by transfusions of blood and to administer oxygen by appropriate means. Recent studies on cytochrome C[18] indicate that this substance is capable of correcting anoxemia under certain conditions, and its use in hepatic disease will, no doubt, be investigated further.

Whatever success has been attained in the treatment of acute and chronic primary hepatic disease has been achieved by following in detail the program described in previous paragraphs. Patience, persistence and attention to every demonstrable abnormality of metabolism are necessary. The results in such hitherto hopeless conditions as portal cirrhosis have been highly encouraging, and not a little of the improvement in surgical results may be due to the application of these principles.

SUMMARY AND CONCLUSIONS

Success in the management of jaundiced patients appears to depend on increased accuracy of diagnosis, especially in the differentiation of obstructive from hepatocellular jaundice. The value of "profile" hepatic functional studies, especially those concerned with urobilinogen metabolism, is discussed.

The indications for surgical intervention in cases of jaundice include (1) the proved or presumed presence of stone, (2) the development of jaundice after cholecystectomy, (3) the presence of associated biliary fistulas and (4) proved complete acholia. The relative contraindications for surgical treatment are discussed with reference to the signs and symptoms of serious primary or secondary hepatocellular injury.

The established principles of medical treatment include a highly nutritious diet, the maintenance of normal hemoglobin and protein levels, the use of vitamins for the correction of specific deficiencies and the employment of lipotropic substances and liver extract.

ABSTRACT OF DISCUSSION

Dr. Ralph Adams, Boston: The common duct has been explored in 35 per cent of the patients operated on for gallstones, which have been found in about 40 per cent of the ducts explored. Dr. Snell has clearly shown the differential diagnostic value of certain laboratory tests, particularly that of the high serum bilirubin, low prothrombin and altered urobilinogen excretion. The purely clinical diagnostic points in carcinoma of the pancreas or bile ducts are progressive jaundice, frequently accompanied by backache, and the other symptoms usually associated with jaundice. In a fourth of the cases at Lahey Clinic there have been associated stone or fibrosis, preventing enlargement of the gallbladder. Every obstructively jaundiced patient should be offered surgical therapy after suitable preparation, unless it can be proved beyond reasonable doubt that the jaundice is caused by parenchymatous hepatic disease. This implies that the surgeon undertaking the care of such a patient should be qualified to perform the pancreatic resection which may be necessary if carcinoma is found or, alternatively, should possess the judgment and the skill required to decompress the gallbladder and bile ducts and to avoid the mishaps and missteps which can seriously influence the chances that the patient may have for successful survival of later resection by a more experienced operator. Three types of decompression are used: a simple stab wound into the gallbladder for the severely jaundiced and ill patients; second, a T-tube placed very low—and let me emphasize "very low"—in the common duct, in case there be fibrosis of the gallbladder or stones, or previous removal of the gallbladder; third, and preferably, a long loop anticolic cholecystojejunostomy with jejunojejunostomy as the first stage procedure. The requirement is the relief of jaundice. The diagnosis may be left in doubt. The diagnostic aids are the diffuse dilatation of the biliary tree or palpable mass in the head of the pancreas. A radical pancreatoduodenectomy has now been done in 34 cases. In 10 cases resection was done in one stage; in 24 ot was done in two stages to gain the advantages of nutritional and chemical preparation before undertaking the radical operation. This period of preparation usually will need to be two to three weeks in length, but a longer period may be required in the presence of severe hepatic damage. An important point, 14 of the 34 patients had carcinoma of the ampulla, the type of obstruction which causes early jaundice, tends to bring the patient at an early stage to his physician and, therefore, constitutes the group in which the more favorable results may be anticipated; and, secondarily, the type of case in which the surgical intervention is easiest. Five of these 34 patients, 15 per cent, died in the hospital; 10, or 30 per cent, have subsequently died, leaving 19, or 55 per cent surviving for a period up to four years. The proper management of the jaundiced patient with carcinoma of the pancreas or bile ducts is a properly staged surgical resection.

Dr. Leon Goldman, San Francisco: In the recognition and preparation of jaundiced patients for surgical intervention a host of liver function tests may be used, and one may be informed or confused by the results of the various tests. There is no test that seems outstanding in the determination of hepatic function. Every jaundiced patient should have the test for prothrombin response to vitamin K performed, not only because of its help in the determination of whether the patient has intrahepatic or obstructive jaundice but also because of the need for knowing what the prothrombin concentration is in the blood, irrespective of whether the patient is going to be operated on. The second test of hepatic function which has definite therapeutic aid is the plasma protein determination. The finding of a low plasma albumin level, with jaundice, suggests that the patient has definite hepatic disease and that, if surgical intervention is indicated, considerable protein therapy may be necessary. One of the pitfalls of liver function tests as a differential diagnostic point in obstructive jaundice is the fact that patients with long-standing, obstructive jaundice also have some hepatic insufficiency, particularly if there is inflammation present, such as is often seen in association with calculi in the common duct. This is borne out by statistics, which show that the mortality rate of patients with stone in the common duct is from two to three times higher than the mortality rate of those patients in whom exploration of the common duct is not necessary. The mortality rate of jaundiced patients with stone in the common duct is also higher, because this operation is indicated more in the upper age groups. An attitude which has been common in the past is that if a patient has a painless type of jaundice, the physician can wait out the case and the diagnosis will show itself; if the type of jaundice is intrahepatic, the jaundice may subside, but if the patient has a malignant growth the jaundice will deepen and the patient's disease will progress. That philosophy is a thing of the past and should not be carried farther; to overlook a diagnosis of carcinoma of the head of the pancreas or carcinoma of the ampulla is to deny the patient a few years of life, or possibly even a cure from cancer of the ampulla or head of the pancreas. An early diagnosis must be made if these patients with cancer, whom Dr. Adams mentioned, are to be successfully operated on with a curative approach rather than to be given merely a sidetracking operation in a palliative manner.

Dr. I. Snapper, New York: Notwithstanding the galaxy of liver function tests which are currently used in the clinical laboratories, there are still conditions in which a new test of hepatic function seems to be in order. In patients who at the same time suffer from syphilis and from gallstones, jaundice which develops after treatment with neoarsphenamine may pose a complicated problem for differential diagnosis. In such patients it is difficult to decide whether the jaundice is due to an obstruction by a stone in the common duct or to the treatment with arsphenamine. The difficulty arises because the common functional tests, when applied to a case of jaundice due to neoarsphenamine, seem to indicate the presence of obstructive jaundice (Hanger). In this quandary the following test has proved helpful. Administration of 6 Gm. of sodium benzoate by mouth leads in normal persons to the excretion of considerable amounts of glucuronic acid in the urine. Administration of the equivalent amount of 5 Gm. of benzoic acid to normal persons does not lead to the excretion of glucuronic acid in the urine. When, however, 5 Gm. of benzoic acid are given to patients with hepatic damage (cirrhosis of the liver, hepatitis or widespread hepatic metastases) the glucuronic acid reaction in the urine becomes strongly positive. In a gallstone patient in whom jaundice develops after neoarsphenamine therapy the excretion of glucuronates in the urine after the administration of 5 Gm. of benzoic acid indicates the presence of hepatic damage. Such a patient has no obstructive jaundice but has an arsphenamine hepatitis, even if all the other current tests seem to point to the presence of an obstruction in the common duct. In such a case operative intervention should, of course, be contraindicated because of the possible danger of hepatic necrosis after the trauma of the laparotomy. This glucuronate test after ingestion of 5 Gm. of benzoic acid can also be used in other instances in which obstructive jaundice has to be differentiated from hepatic jaundice. In regard to methionine therapy, it has been my experience that if a patient with cirrhosis of the liver and hepatic fetor takes methionine the hepatic odor becomes much more decided. Would it be possible that in some cases of hepatic cirrhosis in which deamination is impaired the administration of large doses of amino acids like methionine could give rise to excessive production of toxic metabolites, which ultimately might even precipitate cholemia?

---

[18] Proger, S., and Dekaneas, D.: Some Effects of Injected Cytochrome C on Myocardial and Cerebral Anoxia in Man, J. Clin. Investigation, to be published.

DR. ALBERT M. SNELL, Rochester, Minn.: With regard to Dr. Adams' comments about surgical indications, I can only hope, in approaching the matter of the Whipple operation, that surgeons and internists will pool their data and their resources in the hope that we shall be able to do better. His report was most encouraging. These patients ought to be studied with unusual care preoperatively and postoperatively, if only for the sake of the record. In regard to Dr. Snapper's question about methionine, I have not had a large enough experience with it to say what effect it has on fetor hepaticus. No one knows exactly what produces this symptom, but it is known that it is of great prognostic significance. I shall certainly attempt to get more information on this point. In reference to tests of hepatic function it has been said that their greatest field of usefulness lies in giving the physician time to examine the patient and to take his history. A battery of them are being used, not because physicians are impressed with their individual value but because no one test is particularly reliable, and there is need for all the information which can be obtained concerning many jaundiced patients. As far as hepatitis due to arsphenamine is concerned, one may reasonably question its existence as a clinical entity. In many instances the etiologic factor is contamination of a syringe with human blood containing the virus of infectious hepatitis. The report from a British venereal disease clinic may be recalled, in which, by going back to the individual syringe technic, the workers were able to cause so-called arsphenamine jaundice to disappear. Apparently the condition is a form of homologous serum jaundice. At least, in almost all clinics the incidence of the disease appears to rise at about the third or fourth month after treatment has been begun, corresponding to the long incubation period. Two questions have been handed to me. Do I place any significance on an elevated value for total cholesterol? Yes, I think it means, in most instances, more or less complete biliary obstruction. There is, however, a group of disturbances of lipoid metabolism in which this value may be greatly increased, and in fact the extremely large increases in cholesterol and total lipids are often not the results of biliary obstruction but of primary lipoidosis. Another physician has asked how long the complete biliary obstructive phase of infectious hepatitis may last. So far as I know, the duration of this phase is only a matter of four to five days. There may be a few patients in whom suppression of bilirubin formation is almost complete, and these are the persons who so often have an extensive necrosis of liver cells.

INTRAVENOUS THERAPY OF CIRRHOSIS OF THE LIVER

DANIEL H. LABBY, M.D.

Investigations in recent years have made great advances in elucidating the physiology of the liver and the metabolic processes associated with this organ. The feeding of various experimental diets to animals has demonstrated that the liver is unusually susceptible to nutritional inadequacies and imbalances. The glycogen content of hepatic cells has been observed to decrease remarkably after short periods of starvation, and accumulations of fat within these cells have been produced in experimental animals by diets high in fat and by the administration of various hepatotoxins. A cirrhosis-like syndrome has been produced in animals on diets of low protein and high fat content,[1] and the ability of choline and methionine to prevent the accumulation or to accelerate the removal of hepatic fat (lipotropic effect) has been described.[2]

Studies of cirrhosis in human beings have served to emphasize the importance of the nutritional state. Rao [3] observed that cirrhosis of the liver is of relatively high incidence among Moslems, a population group which does not use alcoholic beverages but in which dietary inadequacies of various types are readily demonstrated. Therefore it seemed likely that improper diet or specific nutritional deficiencies might be factors in the causation of the disease. Later, Patek and Post demonstrated the effectiveness of a balanced and nutritious diet supplemented with vitamins of the B complex group in the treatment of cirrhosis.[4] Patients thus treated were found to have a longer survival period, and in many cases ascites and other manifestations of the disease either disappeared or decreased in severity.

Recently it has been reported that the use of choline in treating patients with cirrhosis of the liver achieves similar therapeutic results.[5]

A study of cirrhosis of the liver was initiated in the Hospital of the Rockefeller Institute for Medical Research in 1941. Investigations included attempts to evaluate the effects of treatment with a diet adequate in calories, protein, carbohydrate and fat, combined with the administration of large quantities of a crude. water-soluble liver extract given intravenously. The inclusion of liver extract in the experimental treatment was prompted by earlier reports of its apparent benefit in cirrhosis.[6]

Dr. Hoagland died Aug. 2, 1946.

The results of therapy at this hospital have been encouraging. Ascites, peripheral edema and other manifestations of the disease have disappeared in many instances. Tests indicate that liver function has improved during the treatment period, and there is evidence of an increase in the survival period in the group of 30 patients studied. This paper describes the treatment used and the observations made which indicate its possible therapeutic effectiveness.

PLAN OF THERAPY WITH INTRAVENOUS CRUDE LIVER EXTRACT

Since so little was known concerning the nature of the factor or factors in liver extract which might be helpful in the management of cirrhosis, it was decided to prepare an extract which was as crude as was consistent with safe administration. The intramuscular route, which is highly satisfactory when commonly-used refined or semirefined extracts of liver are administered in small doses, has proved unsatisfactory when cruder extracts are employed, especially in large dosage. Until information was acquired concerning the optimum dosage for the treatment of cirrhosis, it was thought advisable to give the extract more often and in larger quantities than had been deemed necessary in the treatment of pernicious anemia. Moreover, cirrhosis of the liver of long standing is frequently complicated by general wasting of the musculature, and unless multiple areas of muscle are used for administration of the extract it may be absorbed slowly and thereby increase the hazard of sterile abscesses developing at the site of injection. Likewise, the pain occasioned by the administration of 5 to 10 cc. of crude extract may be so intense as to compel the patient to refuse further treatment.

At the Hospital of the Rockefeller Institute these difficulties inherent in the use of liver extract intramuscularly have been overcome by the development and production over a period of years of a crude, water-soluble liver extract which can be given safely in large quantities by the intravenous route. This extract of dry powdered liver is the water-soluble, alcohol-insoluble portion (Cohn's fraction G[7]) which by permutit treatment[8] has been rendered free of pyrogens and the toxic amines and esters whose injection may occasionally produce an alarming decrease in blood pressure. Final tests of toxicity and sterility have been carried out on selected samples before administration to patients.

Since the Rockefeller formula for the preparation of the extract employed in this study has not been previously reported, it is here given.[9]

Preparation of the Extract.—Powdered liver extract, 440 Gm. (Lilly 343), are added to 1,600 cc. of pyrogen-free distilled water, and the solution is boiled with constant stirring for five minutes. While boiling, 6 cc. of tricresol is added. The mixture is then allowed to cool and is diluted to 2,000 cc. by the addition of distilled water. The material is permitted to stand in a covered glass jar at room temperature for twenty-four hours. The supernatant fluid is then siphoned off, care being exercised not to disturb the fine sediment. The clear solution is passed through a column of permutit contained in a tube of pyrex glass 130 cm. in length and 2.5 cm. in diameter. The permutit filter is made as follows: a small quantity of glass wool is placed in the bottom of the tube and a 25 cm. layer of quartz gravel or alundum, previously ignited and washed, is added; then a 60 cm. layer of permutit is placed on top of the alundum or gravel layer, distilled water being added in amounts sufficient to keep the permutit wet while it is being added to the column. Filtration is facilitated by keeping the tube filled with distilled water until the filtration of liver extract is begun. The first, or dilute, portion of the extract coming through the permutit column is discarded. It is essential that fresh permutit be used for each lot of extract or changed if at any time during the filtration of a given lot of extract a sudden rapid flow indicates that the adsorptive surface of the permutit has been exhausted. The volume of the filtered extract is determined, and 30 cc. of 40 per cent sodium hydroxide per liter is added. The p_H of the solution is carefully adjusted with dilute alkali or acid to between 8.2 and 8.3. The extract is then autoclaved in a pyrex flask, allowing twenty minutes per liter at 166 C., after which the material is filtered while hot through no. 954 Eaton and Dikeman filter paper to remove the flocculent precipitate which forms during autoclaving. Subsequent to this the p_H of the extract is 7.0 to 7.2. The material is then bottled in 10 cc. amounts in sterile vials, and rubber caps are applied. Hypodermic needles are inserted beside the stoppers in order to permit equalization of pressure during the second autoclaving, and the vials are again autoclaved for fifteen minutes at 116 C. The needles are removed, and the stoppers are pushed tightly into the vials with a sterile instrument. The vials are sealed with collodion and stored in the refrigerator until used. Tests for sterility and toxicity are carried out on selected samples of extract in accordance with requirements published in section 36 of the regulations of the National Institute of Health (revised Jan. 26, 1942). The liver extract may be given intramuscularly without further change. For intravenous use, the extract should be diluted and administered slowly after preliminary tests for sensitivity have been carried out.

Since 1941 more than 8,000 intravenous injections of this extract have been given without serious reactions to patients suffering from various types of hepatic insufficiency. It has been given occasionally in daily doses as large as 20 cc. diluted to 50 cc. with isotonic solution of sodium chloride or distilled water and administered intravenously.[10] In the present study, following preliminary tests for sensitivity, doses of this magnitude were administered two to three times weekly. At the onset of therapy and during the phase of ascites, icterus or esophageal hemorrhage the patients were given the full dosage (20 cc. diluted to 50 cc.) at least three times per week. Later, after these manifestations had been controlled, maintenance therapy was continued with the same dosage twice a week.

Allergic reactions from this intravenous liver extract were fortunately infrequent but of sufficient importance to make careful pretesting imperative. To test for sensitivity, from 0.1 to 0.2 cc. of the undiluted extract is given intramuscularly. If within thirty minutes no untoward reaction has occurred (characterized by flushing of the skin, headache, difficulty in breathing, cough or other signs of allergic reaction), slowly inject intravenously 0.5 cc. of the extract diluted with 20 cc. of sterile, pyrogen-free, isotonic solution of sodium chloride, distilled water or 5 per cent dextrose. If, during any injection, the patient complains of headache or shows decided flushing of the skin or signs of allergic phenomena the diluted extract should be given even more slowly. Thereafter a series of graduated doses should be employed to initiate treatment, as illustrated in the following sample schedule:

[9] The valuable technical assistance of Miss Dorothy Sloan in the successful preparation of this material is acknowledged. For the last two years of the study the extract made according to the Rockefeller formula was kindly supplied by Eli Lilly and Company, Lederle Laboratories, Inc., and Parke, Davis & Company.

[10] Hoagland, C. L., and Shank, R. E.: Infectious Hepatitis: A Review of Two Hundred Cases, J. A. M. A. **130**: 615-621 (March 9) 1946.

1st day 1 cc. diluted to 25 cc.
2d day 3 cc. diluted to 30 cc.
3d day 5 cc diluted to 50 cc.
4th day 10 cc diluted to 50 cc.
5th day 15 cc diluted to 50 cc.
6th day 20 cc diluted to 50 cc.
Subsequently, 20 cc diluted to 50 cc. 2-3 times per week

The rate of dosage increment can be varied at will; for example, the time periods between doses may be extended to two or three days in those patients who exhibit minor reactions after any dose. In such cases the dose may also be decreased by one step in the schedule, or the same dosage may be repeated once or twice before proceeding to the next. Solutions should enter the vein at a rate not to exceed 5 cc. per minute. If pronounced flushing occurs, the solution should be injected more slowly or greater dilution should be used.

In only 2 patients, not included in the present study, was the administration of liver extract by the intravenous route considered inadvisable. Both patients were extremely sensitive to liver extract in any form and by any route of administration. Recent experience, however, has shown that, even in the exceptional case of sensitivity to crude liver extract, desensitization with minute doses of extract before administration of the full dose can be safely accomplished.

MATERIAL AND METHODS

The present report concerns the results of treatment of 30 patients with cirrhosis, using intravenous crude liver extract for six months or longer. Twenty-seven of these patients had Laennec's cirrhosis and 3, biliary cirrhosis. In all instances the diagnosis was well established by consideration of the historical details, physical examination, appropriate roentgenologic studies of the esophagus, abdomen and gastrointestinal tract and the use of a wide variety of tests of hepatic function and measurements of pertinent serum constituents. In 14 patients the diagnosis was confirmed by exploratory laparotomy or needle biopsy.

All patients were in the "decompensated" stage of cirrhosis, as indicated by the presence of icterus, edema, ascites or esophageal hemorrhage, singly or in combination. More than half of the patients had experienced some sign of hepatic decompensation one to six months before being given liver extract (table 1). Since the period immediately after decompensation has been demonstrated to be the most hazardous for the survival of patients with cirrhosis,[11] the major portion of the group presented a considerable challenge to the plan of therapy under investigation. No planned selection was exercised in the choice of patients beyond requiring that each case represent manifestly decompensated but not terminal cirrhosis.

The patients were hospitalized when necessary at the Hospital of the Rockefeller Institute and the New York Hospital. Many of the cases were referred from the latter institution for consultation and continuance of their care. When sufficient improvement had been accomplished by a short period of hospitalization, the patients were allowed to join the ambulatory group being treated with intravenous liver extract in the outpatient department of the Rockefeller Institute hospital. Abdominal paracenteses were performed in the hospital or, more frequently, in the outpatient department as the need arose. Diuretics were seldom used.

It is important to point out that a majority of the patients were more fortunate economically than the indigent alcoholic addicts with cirrhosis who are so often encountered in a general hospital service. Most of the patients were able to exercise good judgment in matters of personal hygiene and to apply reasonable intelligence to problems arising in the course of their protracted therapy. This fact made the group a particularly favorable one with which to work, since the importance of abstinence from alcohol and the maintenance of adequate nutrition were readily appreciated by most patients and observed without compromise.

No strict supervision of diet was undertaken beyond instructing the patients to select foods high in protein and rich in carbohydrate; no foods were prohibited if tolerated without distress[12] Lipotropic substances, such as choline or methionine, were not prescribed, since it was believed that these food elements would be plentiful in an adequate dietary intake. Only in those patients exhibiting clinical signs of specific vitamin B deficiency at the onset of treatment were supplements of the vitamin B group prescribed, and these were continued only for the short period required for manifestations of deficiency to be overcome. In their search for medical care 18 patients had received dietary and vitamin therapy from other medical sources before being referred to the Rockefeller Institute hospital. Many had also received short trials of methionine and choline therapy. In all these patients previous management had proved to be ineffective and in no case did the patient consider that he had been benefited.

TABLE 1.—*Historical Data in Thirty Patients with Cirrhosis*

	Patients	
	No.	%
Fatigue	30	100

1 to 5	8	27
6	1	3.3
22	1	3.3
45	1	3.3

An excellent follow-up experience was obtained with this group. Observation periods varied from twenty-one to thirty-eight months, with an average for the group of approximately two years. With little exception the patients reported dependably two or three times a week to receive liver extract intravenously. During this treatment period there was opportunity for close observation of the clinical progress in each case and for the management of the numerous minor medical problems that arise in the course of a chronic illness.

CLINICAL FEATURES

The distribution of the patients by age and sex is given in table 2, and an analysis of the presenting histories is listed in table 1. Fatigue was a complaint common to all patients, and a large number had a history of recent icterus with the onset of hepatic decompensation. Gastrointestinal distress, nausea and anorexia with resulting loss of weight were prominent symptoms. Twenty-one of the 30 patients were chronic alcoholic addicts, and 20 of these had a history of inadequate diet. Of the 9 nonalcoholic patients, 5 had icterus in childhood or adolescence. Seven patients had experienced esophageal hemorrhage. No patients had a history of tropical disease or residence in a tropical country.

Table 2.—*Distribution by Age and Sex of Thirty Patients with Cirrhosis*

41 to 50	8	4	12	40.0
51 to 60	5	3	8	26.7
61 to 70	2	2	4	13.3
Total	19	11	30	

Physical signs indicative of hepatic disease with decompensation were observed in all the patients (table 3). Icterus was a common physical observation. The liver was enlarged in 22 patients, while in 8 it was not palpable and by percussion was reduced in size. Twenty-one patients had ascites, and there was accompanying hydrothorax in 4 of these. In 4 other patients icterus, ascites and esophageal hemorrhage coexisted, indicating an advanced degree of hepatic insufficiency. Esophageal varices were demonstrated roentgenologically in 11 patients. Over 90 per cent of patients displayed palmar erythema, or "liver palms," and spider angiomas. Over 50 per cent of the group gave evidence of hemorrhagic phenomena, such as easy bruising and bleeding gums, in association with depressed prothrombin values.

LABORATORY FEATURES

The innumerable and diverse functions of the liver make it impossible to use any single test as a reliable index of the functional capacity of the liver. Moreover, hepatic failure is a relative matter in which individual functions are attacked selectively and with differing intensity. In approaching the evaluation of a new therapeutic agent it was thought advisable to use a number of different procedures to test the ability of the liver to perform its diverse metabolic functions. The laboratory aspect of the study, therefore, included a wide assortment of measurements and tests which were performed at intervals throughout the period of observation of each patient. These included measurements of the total plasma proteins with determination of the albumin-globulin ratio, the prothrombin time, alkaline phosphatase, serum bilirubin, total cholesterol and cholesterol esters with calculation of the free to total cholesterol ratio, and determination of the carotene and vitamin A levels of plasma. In addition, the cephalin-cholesterol flocculation reaction, the sulfobromophthalein sodium excretion test (5 mg. per kilogram of body weight in a forty-five minute interval) and the thymol turbidity reaction of the serum were determined (tables 4, 5 and 6). The technics employed for these measurements in this laboratory have been reported in detail in a previous communication.[10] Of this battery of tests, the measurement of plasma protein and the albumin-globulin ratio, serum bilirubin, ratio of free to total cholesterol and sulfobromophthalein excretion tests were considered to reflect most accurately the clinical state of the patient and the functional capacity of the liver. These tests, as well as those previously listed, were performed at regular weekly intervals during the acute phase of decompensation. Later they were spaced at greater intervals when less clinical change was apparent and as the course of the disease became better stabilized with continued therapy.

RESULTS

The results of therapy are summarized in tables 4 to 8. Thirteen of the 30 patients were well enough to remain ambulatory throughout the period of observation and treatment. The remainder became ambulatory after a short period of hospital observation, so that by the time therapy was well under way the entire group could be managed in the outpatient department.

One of the first signs of improvement was a return of appetite, which in many instances became hearty after having been practically nonexistent before treatment. Coincident with this, a sense of well-being developed and fatigability diminished. The evidences of improved nitrogen storage were clinically apparent by the reversal of tissue wasting and a gain in body weight (table 7). Although changes of weight in patients with ascites and edema were difficult to evaluate, the appearance of flesh in previously wasted areas left little doubt that tissue regeneration and protein storage had occurred. Many of the patients previously employed continued to work throughout the period of therapy, but in 14 instances illness prevented patients from working. All the patients eventually were able to carry on their work effectively without the recurrence of the distressing fatigability that characterized their period of symptomatic illness (table 7).

* Normal values.

One of the most satisfactory results was observed in the 21 patients with ascites. Most of these patients had submitted to repeated abdominal paracenteses before being seen at the Rockefeller hospital (table 1). In 7 cases the frequency of paracenteses was materially reduced, and in 12 cases, or 57 per cent of the group, there was complete disappearance of the ascites in two to twelve months after the start of therapy (table 8). One patient with ascites for one year before being seen at the Rockefeller hospital had undergone twenty-two paracenteses in that period of time (table 1). After five months of intravenous liver extract therapy the rate at which ascites reaccumulated became noticeably reduced and the intervals between abdominal tapping lengthened progressively. After eighteen months of biweekly liver extract therapy and fifty-three additional paracenteses, the ascites was completely controlled and has now remained so for an additional period of nine months. There was failure to influence the rate at which ascites reaccumulated in only 2 of the patients. As in the other 7 patients with persistent ascites, however, these 2 were better able to tolerate paracenteses, since with improved appetite and restored nutrition they experienced a return of vigor. In this group a phenomenon was frequently observed that suggested a direct effect of intravenous liver extract therapy on the factors which control fluid balance in hepatic disease:[13] occasional patients showed a periodic moderate diuresis several hours after the intravenous injection of liver extract. The diminution and final disappearance of edema and ascites, which proceeded over a period of several weeks, was always associated with a gradual increase in urine volume, which thereafter was sustained (chart 1).

Disappearance of wasting and increase in body weight	28	93.0

Changes in the constituents of the blood and in the results of tests of hepatic function observed during the period of treatment may be seen in tables 4 to 6. Only 43 per cent of patients in the group exhibited a total plasma protein of 6 Gm. per hundred cubic centimeters or higher before treatment. After six months of therapy 73 per cent were in this group, and by the end of two years this figure had risen to 86 per cent. It is apparent that, although the greatest rise in the total protein level occurred during the first six months of therapy, further improvement in several cases was detectable twelve to twenty-four months after the initiation of treatment. The early alterations in total protein were for the most part due to increases in the albumin fraction. Only 22 per cent of the group exhibited albumin levels of 3.5 Gm. per hundred cubic centimeters or higher at

Biol. & Med. **63**: 110-114 (Oct.) 1946; Water Storage and the Movements of Body Fluids and Chlorides During Acute Liver Disease, J. Clin. Investigation, to be published. Ralli, E. P.; Robson, J. S.; Clarke, D., and Hoagland, C. L.: Factors Influencing Ascites in Patients with Cirrhosis of the Liver, ibid. **24**: 316-325 (May) 1945.

the start of therapy, but six months later this group had enlarged to 43 per cent, at the end of one year to 50 per cent and within two years to 66 per cent. Initially the globulin fractions were abnormally elevated in 56 per cent of the group, and these values showed little decrease during the first year of treatment. In many instances the globulin levels rose above the pretreatment level during the early course of therapy. Since this often occurred at the same time that the serum albumin was rising, there was little change in the albumin-globulin ratio until the latter half of the first year of therapy. During this period a slight fall in serum globulin was noted for the group, which fall became more evident during the second year of therapy. Changes in the albumin-globulin ratio were therefore delayed until this late period when, in the presence of sustained and improving levels of albumin, the globulin values began to fall (table 4). The increase in plasma protein concentrations and the ability to maintain efficient metabolic levels of albumin seemed to attest to the improved protein-synthesizing capacity of the liver subsequent to therapy.

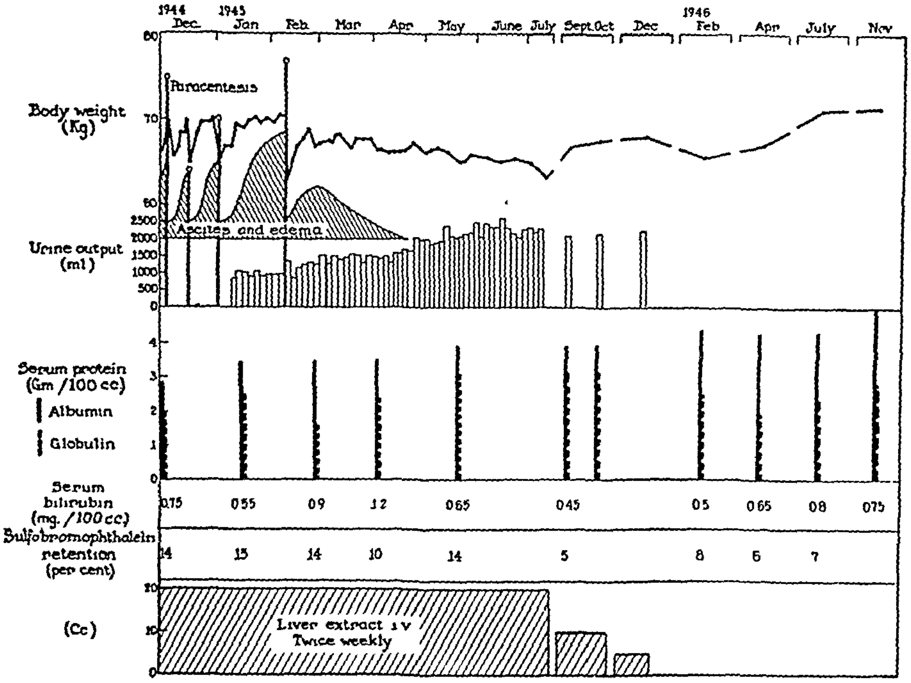

Chart 1 (B S) table 11.—A chronic alcoholic addict had one year of pronounced fatigue, anorexia, icterus and ascites unsuccessfully treated by the family physician with irregular dietary and vitamin therapy; he had forty-five paracenteses prior to treatment with intravenous liver extract. There was improvement in appetite and dietary intake with intravenous liver extract therapy; the disappearance of edema and ascites associated with a rise in urine volume occurred after four and a half months of treatment. Improvement in values for tests of liver function and serum proteins was observed. No relapse has taken place after more than one year of treatment free observation period.

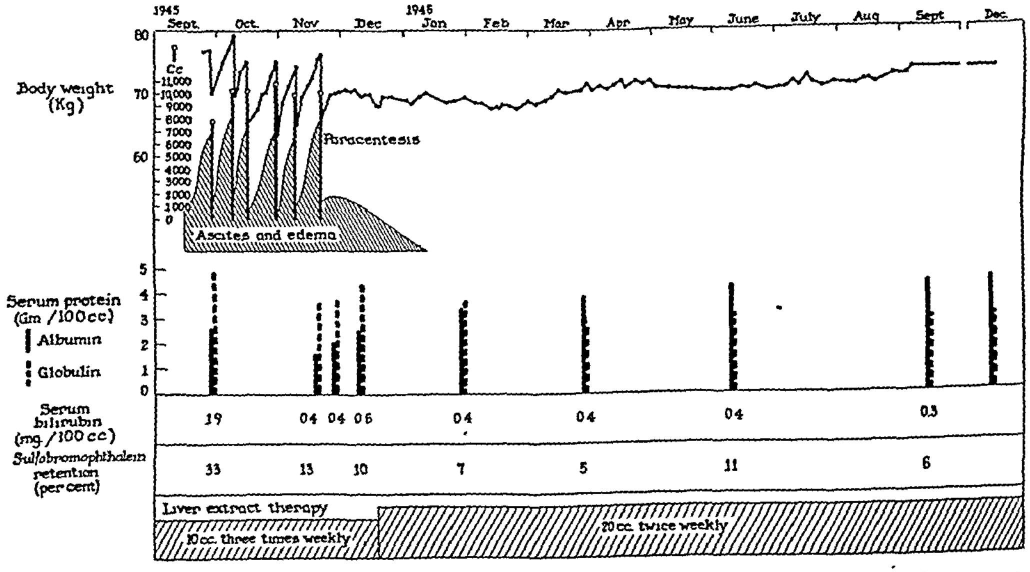

Chart 2 (G. A.).—A man aged 48, a chronic alcoholic addict, had two months of extreme fatigue and complete anorexia, slight icterus, edema, hydrothorax and ascites. The liver and spleen were enlarged; there was a reversal of the albumin-globulin ratio. Disappearance of edema, hydrothorax and ascites occurred before improvement in the plasma proteins and after four and a half months of dietary and intravenous liver extract therapy. Later there was restoration of the plasma protein levels; the patient is still receiving treatment.

The loss of ascites often reflected underlying improvement in the plasma proteins. In several patients, however, the rise in plasma proteins occurred after absorption of the ascites was well established (chart 2). This has been a matter of previous comment.[13]

Seventy per cent of the group showed visible icterus with an accompanying serum bilirubin determination greater than 1.0 mg. per hundred cubic centimeters before treatment, but after two years of treatment 60 per cent had no icterus and a serum bilirubin level of 1.0 mg. per hundred cubic centimeters or less (table 5). Great improvement was noted in the group of patients with initial serum bilirubin concentrations of 3.0 mg. per hundred cubic centimeters or higher. Although 30 per cent of the patients were in this group before therapy, only 12 per cent exhibited serum bilirubin levels of this magnitude after six months of treatment. There was equal improvement in the ability to excrete sulfobromophthalein sodium. Every patient in the group exhibited sulfobromophthalein retention of more than 10 per cent, and half showed more than 30 per cent retention before therapy. After approximately two years of treatment one third of the group exhibited from zero to 10 per cent retention (table 5). There were parallel improvements in plasma concentrations of alkaline phosphatase, carotene and vitamin A and in the free to total cholesterol ratios (table 6). Of all the measurements and tests performed, the cephalin-cholesterol flocculation reaction and the thymol turbidity reaction of the serum proved to be of the least value as accurate indexes of the clinical progress and course of the disease in these patients.

TABLE 9.—*Fatal Cases of Cirrhosis with at Least Six Months' Course of Intravenous Liver Extract Therapy*

Patient	Sex	Age	Clinical Data	Mos of Treatment	Effect of Therapy	Cause of Death
F. C.	♂	33	Nonalcoholic; chronic icterus after inoculation with yellow fever vaccine 3 yrs before; diarrhea, loss of weight and appetite, enlarged liver; A/G * = 2.78/2.85 = 1.0; sulfobromophthalein excretion 37%; bilirubin 3.8 mg./100 cc; "biliary" cirrhosis	10	Improved appetite; weight gain; decreased fatigue	Common duct obstruction with stone; hepatic coma
V. M.	♀	37	Chronic alcoholism; icterus in childhood; 5 mos of high icterus, diarrhea, anorexia and loss of weight; ascites 2 mos; enlarged liver; A/G * = 2.81/3.42 = 0.8, sulfobromophthalein excretion 38%; bilirubin 10.7 mg./100 cc.	3, then lapse of 2 mos., then 14 mos.	Improved appetite; weight gain; decreased fatigue; loss of edema and ascites after 3 mos of treatment, then withdrawal from treatment with recurrence of entire picture of esophageal hemorrhage; reversal again after resumption of treatment	Hemorrhage after tooth extraction, recurrent ascites; esophageal hemorrhage; hepatic coma
E. M.	♀	70	Two attacks of icterus in childhood and youth; nonalcoholic; esophageal hemorrhage followed by icterus, edema and ascites 5 mos later; small liver, large spleen; A/G * = 2.05/2.84 = 0.7; sulfobromophthalein excretion 27%; bilirubin 0.8 mg./100 cc.	13	Improved appetite; weight gain; decreased fatigue; no effect on recurrence of ascites; improved tolerance of paracenteses, 16 performed	Intestinal obstruction due to old pelvic adhesion; postoperative death
H. McK.	♂	63	Fatigue, weakness, anorexia and loss of weight for 10 mos; then icterus, abdominal pain, slight ascites and bleeding gums, enlarged liver and spleen; A/G * = 2.72/3.22 = 0.8; sulfobromophthalein excretion 37%; bilirubin 2.4 mg./100 cc.	8	Improved appetite; decreased fatigue	Hepatic failure with coma
M. S.	♀	52	Nonalcoholic; 2 yrs. of severe icterus, diarrhea, loss of weight, anorexia and weakness; 16 mos of ascites, enlarged liver, no benefit from diet and vitamin therapy; frequent fever with elevation of icterus, 17 paracenteses before liver extract therapy	15	Decreased fatigue, improved appetite, loss of ascites, later increased icterus; recurrence of ascites	Hepatic failure with coma
G. T.	♀	42	Chronic alcoholism; icterus, fatigue and anorexia for 3 yrs; ascites for 2 yrs; enlarged liver, edema; A/G * = 3.41/3.17 = 1.1; sulfobromophthalein excretion 35%; bilirubin 1.9 mg./100 cc	18 Irregular therapy	Decreased fatigue, improved appetite, loss of ascites; weight gain	Active alcoholism during treatment; exsanguinating esophageal hemorrhage 4 mos. after withdrawal from therapy and continued alcoholism
D. B.	♂	66	Nonalcoholic; low protein diet by preference; 3 mos. of wasting, icterus and ascites; small liver, large spleen; esophageal varices; A/G * = 2.73/3.25 = 0.8; sulfobromophthalein excretion 21%	16	Improved appetite, decreased fatigue; tolerated 53 paracenteses at weekly intervals throughout treatment; resumed work and survived an esophageal hemorrhage after 3 mos. of therapy and a laparotomy 9 mos later; no change in rate of accumulation of ascites, massive edema for the last year of life	Severe bronchitis with hepatic coma

* A/G, albumin globulin ratio

In this group of patients treated six months or more with intravenous liver extract, 7 deaths occurred (table 9). Two of the 3 cases of biliary cirrhosis are included in this group. In one (F. C.) the association of common duct obstruction due to stone was a material factor in hastening the patient's death. One fatality (E. M.) occurred in a 70 year old woman with ascites in whom there developed a low grade peritonitis which was followed by intestinal obstruction. At surgical intervention massive pelvic adhesions were found to be responsible for the obstruction and were believed to be a result of radiation therapy undertaken twenty years previously for sterility. V. M. died after an elective tooth extraction, which produced massive uncontrolled hemorrhage followed by recurrence of ascites and hepatic coma. G. T. was a moderately active alcoholic addict throughout her irregular treatment period. Despite this, her ascites had been brought under control. Against the advice of the investigators, she withdrew from therapy and continued to drink heavily. Four months later a massive esophageal hemorrhage resulted in exsanguination and death.

It is considered appropriate that at least a six months' trial of therapy be given before the evaluation of a new therapeutic agent for a chronic progressive disease such as cirrhosis, in which the anatomic, biochemical and metabolic defects are so well established by the time decompensation has occurred. Hence, the large group of patients who were treated less than six months is not the subject of analysis in this communication. Since this may effect some selection, it should be reported that in this inadequately treated group there have been 3 deaths shortly after the start of treatment (table 10). Two of these fatalities were due to massive esophageal hemorrhage in patients with numerous previous hemorrhages; in one (E. E.) treated four and a half months, ascites of one year's duration was controlled before death occurred. The third death was due to coronary occlusion and cardiac failure in a patient who had sustained a coronary occlusion one year previously.

There have been a limited number of observations on the effects of withdrawal from intravenous liver extract therapy. Patient V. M. (table 9) established excellent control of edema and ascites after three months of regular therapy and then voluntarily withdrew. The entire picture of hepatic decompensation rapidly recurred and persisted for the treatment-free period of two months. Compensation was again established when treatment was resumed, and it persisted for fourteen months until shortly before death. Five patients have now completed a series of treatments of arbitrary length varying from ten to eighteen months, and they have been followed further for periods varying from four to fifteen months (table 11). Thus far all hav maintained excellent appetite and intake of food and have exhibited no relapses as determined by clinical findings and tests.

COMMENT

In analyzing the effects of therapy in cirrhosis, one is confronted with the appraisal of many factors that do not lend themselves easily to measurement. One such factor is the management of the many minor problems attending long illness. Since the patients whose cases are reported herein were seen in the outpatient department at least twice a week, many of these problems received prompt attention and care, so that periodic medical supervision of a rather elaborate type was available. How important this may have been in influencing the clinical course and final outcome of treatment is difficult to evaluate. In this regard the effect of abstinence from alcohol and the resumption of a normal intake of food in a person previously a heavy drinker is an important consideration. Moreover, since the majority of patients in the group were of moderate financial means, excellent selection could be exercised in planning individual diets, which were maintained at prescribed standards for foods rich in protein and carbohydrate. The importance of these several factors cannot be underestimated, since each represents in itself a partially effective method of treatment. Before unusual merit is claimed for the use of intravenous crude liver extract, it should be emphasized that this form of therapy has been used successfully only in conjunction with a full regimen of treatment.

TABLE 10.—*Fatal Cases of Cirrhosis After Less Than Six Months of Intravenous Liver Extract Treatment*

Patient	Sex	Age	Clinical Data	Duration of Treatment	Cause of Death
B E	♂	58	Chronic alcoholism; 3 esophageal hemorrhages; icterus, ascites; large liver and spleen	6 wks.	4th esophageal hemorrhage; pneumonia
J L	♂	63	2 yrs gastrointestinal distress; coronary occlusion 1 yr. before; mild icterus, 3 mos. of ascites; large liver and spleen	6 wks regular; no therapy 4 wks.; then 6 wks irregular	Coronary occlusion with cardiac failure
E E.	♀	40	Chronic alcoholism over 2½ yrs.; loss of weight and fatigue; 1 yr. of hydrothorax, edema, ascites and icterus; 6 esophageal hemorrhages; laparotomy; 11 paracenteses; large liver and spleen	4½ mos. regular therapy with increasing appetite, weight gain, decreased fatigability and loss of ascites	7th esophageal hemorrhage

TABLE 11.—*Patients with Cirrhosis Who Completed a Series of Intravenous Liver Extract Treatments and Are Now on Treatment-Free Observation Period*

Patient	Sex	Age	Clinical Data	Mos of Therapy	Effect of Therapy	Mos Since Therapy Terminated	Progress
B S †	♂	58	Chronic alcoholic; 1 yr of ascites, icterus, fatigue and anorexia; large liver and spleen; 45 paracenteses anemia; albumin 3.37 Gm. per 100 cc., globulin 2.03 Gm. per 100 cc.; sulfobromophthalein excretion 15%	13	Increased appetite; weight gain; loss of icterus and ascites; restoration of plasma proteins; albumin 4.99 Gm. per 100 cc., globulin 2.54 Gm. per 100 cc., sulfobromophthalein excretion 7%	13	Continued weight gain, no recurrence of ascites or icterus; protein A/G * = 2.0
J M	♂	58	Chronic alcoholic; 3 mos. of icterus and ascites, anorexia and fatigue, enlarged liver; 3 paracenteses, albumin 2.34 Gm. per 100 cc., globulin 2.43 Gm. per 100 cc.; sulfobromophthalein excretion 42%	16	Increased appetite and loss of fatigability, icterus and ascites; albumin 3.50 Gm. per 100 cc., globulin 4.40 Gm. per 100 cc.; sulfobromophthalein excretion 30%	13	Occasional fatigue; no recurrence of icterus or ascites
P J	♂	59	Chronic alcoholic; enlarged liver for 9 yrs.; esophageal hemorrhage 4 mos. before; ascites, icterus, sulfobromophthalein excretion 22%	18	Increased appetite, loss of fatigability, icterus and ascites; decided improvement in tests of liver function	9	No recurrence of icterus or ascites; increased proteins; sulfobromophthalein excretion 5%. protein A/G * = 2.5
M W.	♂	30	Fatigue and anorexia; chronic alcoholism, enlarged liver, 4 mos. of ascites; albumin 3.12 Gm. per 100 cc., globulin 6.32 Gm. per 100 cc.; sulfobromophthalein excretion 60%	10	Increased appetite; loss of fatigability and ascites; albumin 4.65 Gm. per 100 cc., globulin 2.61 Gm. per 100 cc.; sulfobromophthalein excretion 30%	15	No recurrence of ascites or fatigue; protein A/G * = 1.7
R M	♀	16	Nonalcoholic; cirrhosis after hepatitis; anorexia and fatigue; icterus, ascites for 7 mos.; enlarged liver and spleen, albumin 2.18 Gm. per 100 cc., globulin 3.78 Gm. per 100 cc.; sulfobromophthalein excretion 50%; active nonspecific ulcerative colitis	18	Restoration of appetite and strength; loss of fatigability, icterus and ascites, albumin 4.17 Gm. per 100 cc., globulin 2.33 Gm. per 100 cc.; sulfobromophthalein excretion 12.5%	4	No recurrence of icterus or ascites; no relapse in tests of liver function; continued moderate activity of ulcerative colitis

A full diet, properly planned, should be the first consideration, and appetite therefore becomes a prime requisite. In anorexic patients, whose dietary intake has been compromised by alcoholism and chronic disease of the liver, the intravenous use of crude liver extract in large doses is considered to play its major role by encouraging and sustaining appetite. The vigorous use of vitamins, therefore, becomes less important in the patient with an appetite, who is able to eat adequately and derive essential food elements from natural sources.[14]

The clinical vitamin deficiencies should be treated with the appropriate essential substances, but this form of therapy need not be prolonged much beyond the usually brief period necessary to correct the manifestations of such deficiency.

---

[14] Reprint and Circular Series no 122, National Research Council, 1946, quoted in Present Status of Vitamin Requirements, Editorial, Am. J. Med. **1:** 447-448 (Oct.) 1946. Wilder, R. M.: Misinterpretation and Misuse of the Recommended Dietary Allowances, Science **101:** 285-288 (March 23) 1945

There is some reason to regard cirrhosis of the liver as an intrinsic deficiency disease, in which faulty metabolism of certain essential components of the diet may give rise to syndromes which resemble deficiency diseases in their outward aspects but, unlike the currently recognized deficiency diseases, do not respond in any striking or specific manner to one or a combination of known vitamins.[15] However, this need not be an indication for the use of B vitamins in exorbitant doses, since the concept of faulty metabolism of vitamins of the B complex group in advanced hepatic insufficiency is based thus far largely on speculation and analogy and awaits convincing laboratory proof. Excellent evidence exists for vitamin A,[16] D [17] and K [18] deficiency, however, and the therapeutist need not hesitate for lack of rationale in supplying these substances when confronted by a patient with chronic hepatic disease who exhibits defective dark adaptation, steatorrhea, osteoporosis or low prothrombin values. That these deficiencies are essentially intrinsic will be realized when complete reversal does not result from appropriate substitution therapy.

So little is known about the complex chemical make-up of intravenous crude liver extract that it would be profitless to attempt to indicate what constituent factors might meet the requirements of a disease involving a multiplicity of intrinsic deficiencies, the majority of which are admittedly ill defined. It is conceivable that factors contained within crude liver extract are directed against intrinsic deficiencies as yet unrecognized. Too little methionine and choline are present in intravenous crude liver extract [19] in comparison to the amounts achieved by dietary intake to attribute to these agents alone the beneficial effects produced. It is of interest that small intramuscular doses of crude liver extract have been utilized in several recent investigations.[20] Other forms of nutritional therapy have proved of value in cirrhosis. A growing experience with injectable human serum albumin solutions has shown that this treatment adjuvant is of unique value in those patients with intractably low plasma protein levels, and especially in those who are unable to achieve positive nitrogen balance.[21]

Rest and freedom from undue physical strain are no less essential than diet, especially during critical periods of hepatic decompensation.[22] It is evident from a consideration of the elementary principles of physiology that rest or restriction of activity at once reduces the functional demands on the liver.

A review of experiences [23] in the treatment of cirrhosis with groups of patients comparable in size to our own has shown the two year survival rate to be approximately 45 per cent when dietary forms of therapy are widely supplemented with vitamins.[20b] By contrast, only 22 per cent [20b] to 25 per cent [24] of untreated control patients survived the first two years after decompensation. A comparable group of patients treated with intravenous liver extract has shown a 65 per cent survival rate at the end of a two year period.[24] The 23 surviving patients in our series represent a survival rate of 77 per cent at the end of the same interval.

In many instances such physical, economic and social rehabilitation was accomplished that it was difficult to compare the state of apparent health during the course of treatment with the previous serious clinical state before therapy. The universal experience of returning appetite in the group, with its desirable effect on the storage of protein and the general nutritional state, argues for the reversal of factors active in the production of hepatic decompensation. While it is not unlikely that liver extract may encourage the regeneration of hepatic tissue and assist in restoring to normal the aberrations of water balance, energy metabolism, vitamin storage and enzyme synthesis known to occur in patients with cirrhosis of the liver, such effects remain to be demonstrated by future work. The role of liver extract most easily ascertained clinically is the effect on appetite. That appetite becomes hearty in previously anorexic patients there is little doubt, and in many cases it develops to almost pathologic vigor. The resultant gain in nutrition and its reflection in bodily economy is undoubtedly of critical value in this form of therapy. It is also impressive that with the return of vigor the decompensated cirrhotic patient is better able to tolerate the vicissitudes of chronic illness.

SUMMARY

1. Thirty patients with decompensated cirrhosis of the liver were treated intravenously two or three times a week for six months or longer with large doses of crude liver extract. The period of observation varied from twenty-one to thirty-eight months, with an average of two years for the group.

2. No strict supervision of diet was undertaken, but withdrawal from alcoholic beverages was insisted on, and the patients were instructed to select foods high in protein and rich in carbohydrate; no foods were prohibited if they were tolerated without distress. Dietary supplements of vitamins and lipotropic agents such as methionine and choline were not used, beyond short term vitamin B therapy for those patients with clinical B avitaminosis.

3. Twenty-one patients were chronic alcoholic addicts, and at least 20 of these had a history of inadequate diet. Five other patients gave a history of icterus in youth. Seven patients had had esophageal hemorrhages, and 21 exhibited edema and ascites before treatment.

4. Throughout the period of observation the clinical progress of the patients was closely followed. Numerous tests of hepatic function and measurements of pertinent blood constituents were performed at frequent intervals.

5. A return of appetite and an increase in caloric intake were found to be early signs of improvement and were eventually experienced by all patients. A gain in body weight and control of tissue wasting resulted.

6. In 12 of the 21 patients with ascites there was complete disappearance of ascites within two to twelve months after the start of therapy. In 7 patients the frequency of paracenteses was materially reduced, and in 2 there was failure to influence the rate at which ascites reaccumulated. It was believed that because of the return of appetite and the improvement in nutrition and vigor after therapy the patients were better able to tolerate paracenteses, whenever this procedure became necessary.

7. Improvement in the serum protein and bilirubin levels, as well as in sulfobromophthalein retention and other constituents of the blood and tests of liver function, was observed during the course of treatment.

8. Twenty-three patients, or 77 per cent of the group, have survived two years or more. Five patients treated from ten to eighteen months have been placed on treatment-free observation periods varying from four to fifteen months; none of these has shown detectable clinical or biochemical relapse.

9. On the basis of these observations it is believed that one of the effects of crude liver extract administered in large doses intravenously is to restore and sustain appetite in previously anorexic patients with cirrhosis. Used in conjunction with a full diet, a great nutritional advantage is gained which results in the control of wasting and the restoration of protein storage.

PROPYLTHIOURACIL IN THYROTOXICOSIS

Observations on Fifty-Four Patients

WILLIAM S. REVENO, M.D.
Detroit

Propylthiouracil has been recommended by Astwood and VanderLaan[1] as an effective substitute for thiouracil. Its antithyroid action in rats is approximately ten times that of thiouracil, and while it is more toxic than the latter on a weight basis, it is less toxic in quantities having a comparable therapeutic effect.

Clinical observations on the first 52 patients treated[1] point out that with few exceptions, 50 to 75 mg. propylthiouracil a day is an adequate initial dose, while 25 to 50 mg. a day is sufficient for maintenance. The antithyroid action is less intense than that of thiouracil; myxedema and thyroid enlargement have occurred only infrequently, and side reactions, not at all. From this study it appears that the new drug has approximately five times the activity of thiouracil, with few if any of the obstacles presented by the latter.

Fifty-four patients have been treated with propylthiouracil by me during a period of four months. Among 18 of these who had not received previous treatment, 13 (7 women and 6 men) had toxic nodular goiter and 5 (4 women and 1 man) had toxic diffuse goiter.

Thirty-seven patients still on varying maintenance doses of thiouracil were given the new agent instead. Of these, 22 (17 women and 5 men) had toxic nodular goiter and 14 (10 women and 4 men) had toxic diffuse goiter.

Five patients who had been unable to take thiouracil because of drug fever or urticaria were also included in the study. Three of these had toxic nodular goiter, 1 had toxic diffuse goiter and 1 had essential hypertension with normal thyroid function.

RESULTS IN PREVIOUSLY UNTREATED PATIENTS

Ten patients with toxic nodular goiter responded to the drug with an abatement of symptoms, gain in weight and lowering of the basal metabolic rate within four weeks on doses of 50 to 150 mg. a day.

Three of this group requiring only 50 mg. of the drug a day showed a drop in the basal metabolic rate from plus 15 to minus 12, plus 20 to plus 6 and plus 9 to minus 2 per cent. One patient died of acute myocardial infarction at the end of one month, but the other 2 have been maintained for three and two months, respectively, on the same dose.

Four of this group required 75 mg. of propylthiouracil per day. The basal metabolic rate of 1 changed from plus 27 to minus 11, 1 from plus 12 to minus 6, the third from plus 15 to minus 8 and the fourth from plus 41 to zero per cent. The first and second patients have required the same dose for maintenance, the symptoms of the third have been controlled with 50 mg. a day but the dosage of the fourth has been increased to 150 mg. a day.

In 2 patients control was achieved on 100 mg. of the drug daily, 1 showing a drop from plus 27 to plus 5, the other from plus 11 to minus 4 per cent. Both have required the same dose during three months and one month, respectively.

One patient with an initial basal metabolic rate of plus 12 per cent was given 150 mg. of the agent daily. In two weeks the improvement was decided, with the basal metabolic rate down to minus 5 per cent. This level was maintained during the following month on 75 mg. a day.

The symptoms of 3 patients have not been fully controlled in two to three months of treatment. Symptomatic improvement with gain in weight has occurred, but the expected drop in the basal metabolic rate has not followed:

One patient with an initial rate of plus 50 per cent was given 75 mg. of the drug daily for sixty-three days, with depression of the basal metabolic rate to plus 30, plus 31 and plus 29 per cent. The dosage was increased every two weeks to a present level of 200 mg. a day. No reduction in the basal metabolic rate followed after two weeks at this dosage level.

The second patient was cautiously started on a dosage of 25 mg. a day because drug fever had developed when she was taking thiouracil. The initial basal metabolic rate of plus 15 per cent has moved to plus 18 per cent during three months in which the dose was being slowly increased to 75 mg. propylthiouracil daily.

The third patient started with a basal metabolic rate of plus 21 per cent, which remained unchanged on 75 mg. of the drug a day for four weeks, 100 mg. for two weeks and 150 mg. for two more weeks.

It is perhaps significant that these 3 patients were between 60 and 70 years of age and they had had nodular thyroids for several years, factors which would make for slow response to treatment.

Of the 5 patients with toxic diffuse goiter, 1 showed improvement in four weeks, the basal metabolic rate moving from plus 11 to minus 4 per cent on 75 mg. of the agent daily, with maintenance on 50 mg. a day during the subsequent month.

From the Department of Medicine, Harper Hospital and Wayne University College of Medicine.

[illegible] was supplied by Dr. Stanton M. Hardy, Lederle [illegible] River, N. Y.

[1] [illegible] and VanderLaan, W. P.: Thiouracil Derivatives of Greater Activity for the Treatment of Hyperthyroidism, J. Clin. Endocrinol. 5:424 (Dec.) 1945.

In a second patient with basal metabolic rate of plus 12 per cent, the rate showed no change during sixty-five days on a dosage of 75 mg. daily, then dropped to minus 2 per cent after two weeks on 100 mg. of the drug a day.

In a third patient with recurrent hyperthyroidism drug fever developed after forty-one days' treatment.

A fourth patient with diabetes and recurrent hyperthyroidism showed an increase of the basal metabolic rate to plus 25 per cent after two weeks on a dosage of 75 mg. propylthiouracil a day, then dropped to plus 7 per cent after two weeks on 100 mg. a day. When the rate increased to plus 10 per cent in another two weeks the dose was increased to the present level of 150 mg. daily. No improvement in the diabetes has been observed.

The fifth patient, a Negro man aged 40 with a fulminating thyrotoxicosis, improved symptomatically during the first five weeks of treatment with 75 mg. a day, but the basal metabolic rate did not change from the initial plus 41 per cent. There was an increase in the rate to plus 53 per cent during the next two weeks on 100 mg. of the drug a day. A drop to plus 24 per cent and a gain in weight of 4 pounds (1.8 Kg.) occurred during the next two weeks on a dosage of 150 mg. a day.

In this small group the 2 patients with a mild form of the disease responded relatively promptly to a dosage of 75 to 100 mg. propylthiouracil daily. The 2 with a more severe disturbance are still not fully controlled on 150 mg. of the drug a day.

In summary, 10 patients with toxic nodular goiter and 2 with toxic diffuse goiter responded to treatment within four weeks on dosages of 50 to 150 mg. of the drug daily and have maintained their gains. The symptoms of 3 with toxic nodular and 2 with toxic diffuse goiter have not yet been fully controlled over a period up to three months on present doses between 75 and 200 mg. daily. These results are not to be classed as failures, since the patients have not been treated long enough.

RESULTS OF THE SUBSTITUTION OF PROPYLTHIOURACIL FOR THIOURACIL

A group of 22 patients with toxic nodular goiter (17 women, 5 men) and 14 with toxic diffuse goiter (10 women, 4 men) had been on daily maintenance doses of thiouracil ranging from 100 to 400 mg. for from one to eighteen months. To compare the effective maintenance doses and to determine the relative potencies of thiouracil and propylthiouracil, the latter was substituted in the treatment of these patients. Astwood's recommended average maintenance dose of between 25 and 50 mg. compared with the average maintenance dose of 100 to 300 mg. thiouracil yields an approximate equivalent of 25 mg. of the former for 100 mg. of the latter. Changes in medication were made on this basis, the initial dose being 25 mg. propylthiouracil a day, with increases made only when indicated.

Of the 22 patients with toxic nodular goiter, 16 who required 100 to 200 mg. thiouracil have remained as well controlled on an average of 35 mg. propylthiouracil for each 100 mg. thiouracil. Six patients formerly given 200 to 300 mg. thiouracil have not been as well controlled on an average of 33 mg. of the new agent per 100 mg. thiouracil.

Seven of the group in which toxic diffuse goiter was controlled by 100 to 200 mg. thiouracil did as well on an average of 29 mg. of the new drug for each 100 mg. of thiouracil. Symptoms of the remaining 7 patients who required from 100 to 400 mg. thiouracil were not adequately controlled with an average of 30 mg. propylthiouracil substituted for each 100 mg. thiouracil.

In 23 of the 36 patients control was adequate when an average of 32 mg. propylthiouracil was substituted for each 100 mg. thiouracil, while in the remainder inadequate control followed the use of 31.5 mg. of derivative drug. Accordingly, somewhat more than 32 mg. of the new drug appears to be the equivalent of 100 mg. thiouracil for suitable maintenance. For the initiation of treatment a dose of 128 to 192 mg. propylthiouracil should be equivalent to the average starting dose of 400 to 600 mg. thiouracil, giving the new drug a potency value three times that of thiouracil.

TOXICITY

A group of 5 patients unable to take thiouracil because of toxic reactions was started on propylthiouracil. Four had had typical attacks of drug fever, which cleared when administration of the drug was stopped and recurred when it was resumed. In the fifth there had developed urticaria, which behaved similarly in relation to the drug. Three patients had been taking 300 mg. thiouracil a day and 2 patients 600 mg. before the initial attack.

All these patients have now been taking propylthiouracil for four months without any sort of reaction. In 2 the hyperthyroidism is controlled by 50 mg. of the drug daily; in one, by 75 mg. daily, and in the fourth control has not yet been achieved with 75 mg. daily. The fifth patient, who has essential hypertension, is taking 150 mg. a day without difficulty.

It appears that patients who have been unable to take thiouracil are capable of handling propylthiouracil successfully. However, the new drug has toxic potentialities of its own, as demonstrated by the following instance of drug fever.

In a white woman aged 51, who had had a thyroidectomy in 1922, there developed recurrent hyperthyroidism with tachycardia, loss in weight, tremor, blood pressure of 160 systolic and 90 diastolic and a basal metabolic rate of plus 20 per cent. For many years she had suffered from "rose fever" and had been allergic to many substances. On April 23, 1946 she was started on 25 mg. propylthiouracil three times a day. Nausea developed two days later and recurred intermittently during the next four weeks. On May 21 the symptoms had improved only slightly and the basal metabolic rate was still plus 19 per cent, so the dosage was increased to 100 mg. of the drug daily. On May 29 the nausea was worse, and on June 3, forty-one days after the start of treatment, there developed headache, chills, sore throat and a fever of 103 F. The leukocyte count was 12,000, with the polymorphonuclears 70 per cent. Administration of the drug was stopped, and the attack subsided within three days. One week later treatment with the drug was resumed, and four hours after administration of the second 25 mg. tablet there was recurrence of the chills, aching, sore throat and fever. The attack subsided promptly, and no more of the drug was given.

Evidence of toxic effect on the blood or blood-forming tissues has not been noted in this series of patients. Blood counts were at first performed every week, then every two to four weeks. In no instance was there leukopenia, granulocytopenia or anemia.

COMMENT

The experience in treating 54 patients with propylthiouracil coincides in many respects with that of Astwood. Positive antithyroid action was observed, and instances of myxedema or thyroid enlargement did not occur. However, the inability to bring the symptoms of nearly all the patients under control within a period comparable to that experienced with thiouracil may be attributed to too low dosage of the new drug. This should not detract from the antithyroid value of propylthiouracil for it must be recognized that because of its demonstrated potency in rats as ten times that of thiouracil, cautious use in human beings was clearly prescribed. Under the circumstances, a small initial dose, to be increased as indicated, seemed both safe and logical, even though it might postpone the desired control. This approach is exactly the opposite to that used with thiouracil, in which the direction was from a maximal toward a minimal dose, and may well account for the seeming difference in action.

Comparison of the control achieved by the two drugs in a group of patients formerly controlled with thiouracil and transferred to propylthiouracil indicates that it is necessary to use at least 32 mg. of the new drug to achieve the same action as that of 100 mg. of the old. Thus one may assign to propylthiouracil a potency value in man three times that of thiouracil, with the optimal initial dose between 120 and 190 mg. of the drug.

Of particular interest is the observation that 5 patients for whom thiouracil was toxic are able to take the new drug without difficulty. However, propylthiouracil has toxic potentialities of its own, for in 1 patient in the series there developed typical drug fever. While there were no other toxic reactions in this series it does not follow that these may not occur with the administration of larger doses of the drug.

Of the two antithyroid drugs, propylthiouracil, though its action is slower at present dosage levels, is much safer than thiouracil. While faster action may follow larger doses, toxic reactions may also occur, for propylthiouracil is still the more powerful of the two drugs.

SUMMARY

In a group of 18 previously untreated patients with thyrotoxicosis, 11 responded with abatement of symptoms, gain in weight and return of the basal metabolic rate to normal within four weeks on a dosage of propylthiouracil ranging from 50 to 150 mg. a day. One patient responded after 11 weeks' treatment, and in 1 drug fever developed after forty-one days. Five patients showed varying degrees of response just short of complete control because of too low dosage.

Thirty-six patients on maintenance doses of thiouracil were given propylthiouracil instead. The disease of 23 continued under satisfactory control while that of 13 was not controlled as well, again because of too low dosage. Apparently it takes at least 32 mg. of the new drug to match the effect of 100 mg. thiouracil, which would make the potency of the former three times that of the latter. An effective initial dosage comparable to 400 to 600 mg. thiouracil should accordingly be 120 to 190 mg. propylthiouracil daily.

Five patients unable to take thiouracil because of toxic reactions did not experience difficulty with the new drug.

In 1 patient there developed typical drug fever, but no other toxic reactions appeared in the rest of the group.

Propylthiouracil is a potent antithyroid agent fully as effective and much safer than thiouracil, although it is not incapable of producing toxic reaction.

TYPHUS FEVER IN THE UNITED STATES ARMY FOLLOWING IMMUNIZATION

Incidence, Severity of the Disease, Modification of the Clinical Course and Serologic Diagnosis

COLONEL JOSEPH F. SADUSK Jr.
Medical Corps, Army of the United States

Entry of the United States into World War II with exposure of our troops to epidemic (louse-borne) typhus fever in many parts of the world called for the use of adequate protective measures against this disease. One important aspect of this protection was the compulsory immunization with typhus vaccine of all soldiers going to or stationed in areas where epidemic typhus was present.

The purpose of this paper is to report on the excellent protection afforded the personnel of the United States Army by this prophylactic immunization, to record in a limited number of cases in which adequate clinical records have been collected the severity of the disease and the modification of the clinical course and to discuss methods of serologic diagnosis in those persons who contracted epidemic typhus subsequent to vaccination. The incidence of typhus fever in the entire United States Army during the war years, 1942 to 1946 inclusive, is also reported.

EPIDEMIC TYPHUS VACCINE

Subsequent to the demonstration by Ricketts [1] almost forty years ago of micro-organisms which now bear his name, the study of rickettsial diseases has received increasing attention. Since these diseases in man are usually serious and not infrequently fatal, it is not surprising that many investigations have been directed toward the production of prophylactic vaccines,[2] particularly for epidemic typhus fever.

It was early appreciated that persons recovering from these infections exhibited evidence of considerable immunity to subsequent reinfection, and efforts were therefore made, in the absence of adequate protection from killed vaccines, to produce a subclinical or modified infection with the causative organisms. The record of the use of living epidemic typhus vaccine presents a series of frank failures. Investigations based on the use of attenuated murine strains likewise led to results of doubtful value. Satisfactory immunity was developed only at the price and risk of the development in a patient of an active infection with murine typhus. Some patients died; this danger together with other dangers of the use of a living vaccine have been pointed out.[3]

With the growing realization of the dangers of the use of living vaccines, increasing efforts were directed toward the study of killed vaccines. The early work of da Rocha-Lima [4] and Weigl [5] on the use of killed suspensions of infected lice or infected feces of lice indicated that favorable results might be attained. These meth-

ods, together with the use of other procedures such as suspensions of organisms obtained from the peritoneal cavity of the rat[6] or from rodent lungs,[7] were not, however, practical for large scale immunization.

Subsequent to the studies of Cox[8] in 1938, which demonstrated that rickettsias of the Rocky Mountain spotted fever and typhus groups could be grown in the yolk sac membranes of the developing chick embryo, Cox and Bell[9] in 1940 prepared an epidemic typhus vaccine based on the use of this tissue as a culture medium. This vaccine, which consisted of a killed suspension of Rickettsia prowazeki grown in the yolk sac membrane of the chick and purified by centrifugation, protected guinea pigs against challenge with the virus. Subsequent modifications, such as Craigie's[10] ether extraction and the inclusion of a so-called soluble antigen,[11] led to a vaccine that was satisfactory not only from the point of view of potency but also from the aspect of commercial production. Indeed, production in biologic houses in the United States during the World War II years reached as high as 75,000,000 cc. per year.

The epidemic typhus vaccine used by the United States Army consists of a 10 per cent yolk sac suspension of the Breinl strain of R. prowazeki extracted with ether. The vaccine contains both rickettsial bodies and soluble antigen.

Since early 1942 all United States Army personnel going to or stationed in areas in which epidemic typhus fever is present have received this vaccine. Until the fall of 1943 the initial vaccination consisted of three injections of typhus vaccine, 1.0 cc. each, administered subcutaneously at an interval of from seven to ten days, with stimulating or booster doses being given every six months in endemic areas. With increase in potency due to improvements in production, the initial immunization series was reduced in mid 1944 to two doses of vaccine and the stimulating dose was given at the beginning and in the middle of the typhus season (November 1 and February 1 in the northern hemisphere).

INCIDENCE AND MORTALITY OF TYPHUS FEVER

Official reports of communicable diseases which all Army organizations are required to make to the War Department through appropriate channels do not differentiate between the various members of the typhus group. Epidemic typhus, murine typhus and scrub typhus (tsutsugamushi fever) are included in these reports under the general term of typhus fever. It is possible, however, to obtain figures of a reasonable degree of accuracy for these specific diseases by grouping the cases under one of the three members of the typhus-like group according to geographic locality. For instance, it is evident that all cases of typhus fever contracted in and reported from the continental United States are murine typhus. Likewise, from epidemiologic data and detailed studies of case records, it is reasonable to suppose that cases of typhus fever reported from the Southwest Pacific and China-Burma-India areas are tsutsugamushi fever, although it is possible that a small number of these cases may actually be murine typhus. On a similar basis, cases reported from the European, Mediterranean and Africa-Middle East theaters fall into the epidemic typhus group.

In table 1 are recorded the official War Department figures[12] for typhus fever in the entire United States Army during the period Jan. 1, 1942 to Dec. 31, 1945. These figures are expressed in cases per year and in admission rates per 1,000 per year. On the right side of the table are given the total number of cases for the 1942 to 1945 period of epidemic typhus, murine typhus, and tsutsugamushi fever. It is believed that these data are reasonably accurate.

From table 1 it can be seen that there were 64 cases of epidemic typhus, 603 of murine typhus and 6,685 of tsutsugamushi fever reported in the Army for the war years, 1942 to 1945 inclusive.

When the repeated exposure of American troops is considered it is remarkable that there were only 64 cases of epidemic typhus. However, this low incidence of epidemic typhus cannot be necessarily attributed to prophylactic immunization with typhus vaccine because other methods of protection (notably the use of insecticide powders such as MYL powder consisting of 0.2 per cent pyrethrins, 2 per cent N-isobutylundecylenamide, 2 per cent 2,4-dinitroanisole, and 0.25 per

[12] The Medical Statistics Division, Office of the Surgeon General, War Department, Washington, D. C., supplied the basic data from which table 1 was compiled.

cent of a mixture of isopropyl and diisopropyl cresols, in an inert diluent such as pyrophyllite and DDT powder [4,4′-dichlorodiphenyltrichloroethane] to prevent lousiness) were routinely employed. The question of whether or not vaccine will effectively reduce the incidence of epidemic typhus has not been conclusively demonstrated because of the difficulty of setting up an adequately controlled experiment in a human population on a large scale.

There are certain recent studies, however, which indicate that typhus vaccine prepared from the yolk sac membrane of the embryonated chicken egg will prevent or at least materially reduce the incidence of naturally acquired epidemic typhus. The results of the studies of Stuart-Harris[13] and Sachs[14] on typhus in the British Army suggest that reduction in incidence is effected by such immunization. Gilliam,[15] in a recently reported analysis of the effect of Cox type vaccine in preventing epidemic typhus fever among employees of the Cairo Fever Hospital at El Abbasa, Egypt, during the period from January to June, 1943, presents evidence which again suggests that adequate vaccination affords protection against a subsequent attack of louse-borne typhus.

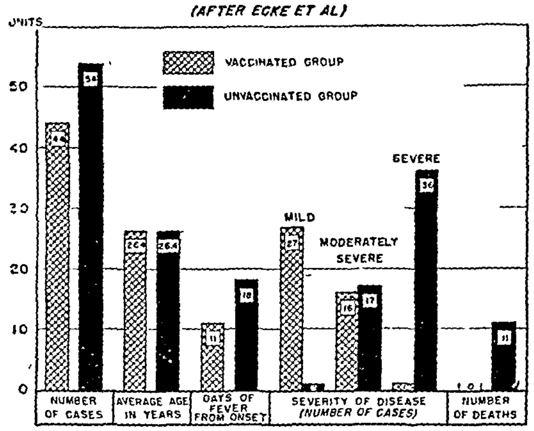

Chart 1.—Graphic representation of the clinical comparison of vaccinated and unvaccinated groups of typhus fever cases among employees of the Cairo Fever Hospital (after Ecke, Gilliam, Snyder, Yeomans, Zarafonetis and Murray[16d]).

On the other hand, there is universal agreement as to the effect of such immunization in reducing the case fatality rate.[16] In a carefully controlled investigation carried out among vaccinated and unvaccinated employees of the Cairo Fever Hospital, Ecke and his colleagues[16d] demonstrated a remarkable difference in not only the case fatality rate but also the clinical severity of the disease. They contrasted a group of 44 cases of epidemic typhus occurring subsequent to immunization with Cox type vaccine with a control group of 54 cases of typhus occurring without benefit of such prophylactic immunization; there were no deaths among the vaccinated group, but in the unvaccinated group there were 11 deaths. As to the severity of the disease, there were 27 cases classified as mild and 1 case classified as severe in the vaccinated group; in striking contrast to this, in the unvaccinated group there was only 1 case classified as mild and there were 36 cases classified as severe. There were 16 cases in the vaccinated group and 17 cases in the unvaccinated group which were classified as moderately severe. The average age of patients in both groups was 26.4 years. These facts are graphically illustrated in chart 1.

Both Stuart-Harris[13] and Sachs[14] reported a considerable reduction in mortality from epidemic typhus in the British Army following the institution of prophylactic immunization. Their reports show that the case fatality rate dropped to less than half the rate observed prior to immunization.

In the American Army there has not been a single death from epidemic typhus reported to the War Department during the period 1942 to 1945. This fact is perhaps the most striking observation made in this report and can be ascribed to prophylactic immunization with the Cox type of ether-extracted typhus vaccine. In my opinion the case fatality rate from epidemic typhus should be practically nil when adequate prophylactic immunization with this type of vaccine is practiced.

There is no evidence to indicate that epidemic typhus vaccine confers substantial immunity against infection with murine typhus in the human subject.

REPORT OF CASES

Adequate clinical records or abstracts of 5 cases were obtained and are briefly reported here. Clinical data pertaining to these cases are summarized in table 2, and serologic findings and typhus immunization records are recorded in table 3. It is hoped that a subsequent analysis of additional cases may be reported at a later date when clinical records have been collected from overseas and appropriately filed.

Case 1.—A man aged 41, an officer and a member of the United States of America Typhus Commission, was engaged in typhus research work in Cairo, Egypt, with another officer (case 2) for almost a month before the onset of disease. They were both daily exposed to infection with typhus by examining patients, picking infected lice off rabbits and patients and handling and grinding infected louse feces for injection into experimental animals. In the preceding two years this officer had received a total of 22.0 cc. of vaccine in single 1.0 cc. doses. Five cubic centimeters of this vaccine was of an experimental lot and contained both epidemic and murine virus. The last dose of vaccine was received on March 1, 1944. The result of serologic examination prior to infection was as follows: on March 21 and April 4, 1944 the Weil-Felix reaction was negative but complement fixation was 1:8 with epidemic antigen and 1:4 with murine antigen.

On May 22, 1944 the patient experienced a mild headache and general malaise and felt feverish. Although the headache became severer and the temperature ranged between 100 and 101 F. during the next three days, he continued with his typhus research activities. On the fifth day, May 26, he took to his bed because of headache, fatigue and malaise. His backache was intense. The next day he reported to a medical dispensary; physical examination revealed a few pink papules on the left palm and wrist, a temperature of 99.2 F. and a pulse rate of 100. The rash had disappeared by the following morning, and except for a mild headache, anorexia and sense of fatigue the patient did well on rest in bed in his quarters, reporting daily to the dispensary. He was afebrile by May 28 and was permitted to remain out of bed on May 31.

Prior to the onset of typhus, the Weil-Felix reaction was negative with both Proteus OX 19 and OX 2 antigens and the complement fixation titer was 1:8 with epidemic antigen

* Cox type ether-extracted epidemic typhus vaccine.
† Five cubic centimeters of this vaccine was of an experimental bivalent type containing epidemic and murine rickettsias.

and 1:4 with murine antigen. By the end of the first week of disease the Proteus OX 19 titer rose to 1:20, and in the second week it rose to 1:80. It reverted to negative in the fourth week. The complement fixation titer rose rapidly to attain a titer of 1:1,024 in the second week. Almost two years later the complement fixation (with epidemic antigen) was still positive with a titer of 1:10.

Case 2.—A man aged 35, an officer and a member of the United States of America Typhus Commission, was engaged in typhus research work in Cairo, Egypt, with another officer (case 1) for over a month prior to the onset of illness. Although he was exposed to the disease daily, he recalled that he was dangerously exposed on June 11, 1944 when he assisted with the handling and grinding of infected louse feces in large amounts. In the period from Dec. 23, 1941 to Oct. 10, 1943 he received a total of 12.0 cc. of typhus vaccine in 1.0 cc. increments. On Nov. 22, 1943 he received 1.0 cc. epidemic typhus vaccine and on April 10, 1944 an additional and final dose of 1.0 cc. of the vaccine. Although the Weil-Felix reaction was negative with both Proteus OX 19 and Proteus OX 2 antigen, the complement fixation titer with epidemic antigen was 1:8 three days before and eleven days after the patient received the last dose of vaccine.

On the morning of June 23, 1944 the patient awakened with a mild but troublesome frontal headache which persisted throughout most of the day. The next day the headache recurred together with malaise and easy fatigability. His temperature was 101 F. These symptoms persisted with such an increase in both severity and extent of the headache that he was admitted to the hospital late in the afternoon of the next day, June 25. The following day his temperature was 100.4 F., his pulse rate was 80, his respiratory rate was 20 and his blood pressure was 106 systolic and 60 diastolic. Although he did not appear acutely ill, he complained of headache, sensations of chilliness and nausea. Physical examination revealed only a well defined injection of the scleral conjunctivas. Later in the afternoon his temperature rose to 102 F. and a diffuse macular eruption appeared over the anterior part of the chest, arms, shoulders and flanks with an erythematous blush that disappeared on pressure. He continued that afternoon and night to experience slight chills. By the next morning the rash had definitely faded but his headache, which was now generalized, became exceptionally severe. Chills continued, and he appeared decidedly ill. There were intermittent, drenching sweats, and he complained of severe backache and general malaise. The temperature rose to 103.2 F. that night, but the pulse rate was only 90. The respiratory rate was normal. Although the temperature fell to 99.2 F. by the following morning (June 28) and remained below 100.6 F. throughout the course of the day, severe headache, malaise, sweating and occasional chills persisted. He vomited several times, and on one occasion there was a transient amnesia. During the next two days these symptoms still persisted but the temperature remained relatively low and the rash became increasingly less evident, disappearing completely by July 1. On June 29 the physician reported that the patient appeared to be disoriented for a brief period, but this was not confirmed and was later denied by the patient. From June 30 on, there was rapid and progressive improvement (chart 1) with fall in temperature by rapid lysis, subsidence of headache, malaise, nausea and vomiting and rapid increase in serologic titers for typhus fever. On June 30 there was a left earache, but this disappeared within forty-eight hours without specific therapy. The temperature was normal by July 3. On July 5 the patient was permitted to be out of bed, and he was discharged on the following day as an ambulatory patient.

Chart 2.—Clinical course and early serologic data in case 2, an example of a moderately severe case of epidemic typhus in a vaccinated person.

During the course of the patient's stay in the hospital there was no pronounced hypotension. On June 26, the day of admission, the red blood cell count was 4,600,000, the hemoglobin was 95 per cent and the leukocyte count was said to be 6,300 with 45 per cent stab cells, 33 per cent polymorphonuclear neutrophils, 20 per cent lymphocytes and 2 per cent monocytes. On July 3 examination of the blood was as follows: red cells 4,650,000, hemoglobin 95 per cent, leukocytes 5,000 with 15 per cent stab cells, 53 per cent polymorphonuclear neutrophils, 18 per cent lymphocytes and 14 per cent monocytes. Urinalysis on June 26 was negative. The color was clear amber, and the specific gravity was 1.010. Tests for albumin and sugar were negative.

Serologic tests were performed daily during the early acute phase of the disease. The Weil-Felix reaction with Proteus OX 19 antigen remained negative until the eighth day, when it became positive in a titer of 1:20. It then rose rapidly, reaching a top figure of 1:1,280 on the nineteenth day. It was still positive at 1:80 on the one hundred and twenty-fourth day, but when next checked almost two years after the onset of the disease, it was found to be negative. Complement-fixing antibodies began to rise by the end of the first week of disease, reaching a peak with epidemic antigen of 1:512 by the nineteenth day. The titer began to fall after the thirty-first day, and when last checked almost two years later the titer was still positive at 1:20. Specific rickettsial agglutinations were negative at that time.

Case 3.—A man aged 36, an officer and a member of the United States of America Typhus Commission, was engaged in typhus control work in Hokkaido, Japan. On Nov. 10, 1945 he was heavily exposed in the room of a Japanese hospital to dust containing suspended louse feces from the clothing of a patient with an active typhus infection. From Feb. 17, 1944 to July 28, 1944 he had received a total of 4.0 cc. of typhus vaccine in 1.0 cc. doses. On May 9, 1945 and Oct. 1, 1945 he received additional 1.0 cc. doses of the vaccine. On June 6 and Aug. 4, 1945, serologic examination was as follows: the Weil-Felix reaction was negative; complement fixation was 1:10 with epidemic antigen and negative with murine antigen, and rickettsial agglutination was 1:40 with epidemic antigen and negative with murine antigen.

On Nov. 22, 1946 the patient experienced sensations of chilliness and generalized malaise. The next day headache, apathy, anorexia and irritability appeared. These persisted during the next two days with chilliness, and although the patient felt feverish he did not take his temperature. On the fifth day the temperature was 101.8 F., the pulse rate was 88 and the respiratory rate was 20. Headache became severer and was predominantly bitemporal. A persistent dry hacking cough set in, and the patient vomited once. The next day, the sixth day of disease, he refused hospital admission but finally took to bed in his quarters. The headache became excruciating in severity, the temperature rose to 102.2 F. and nausea and cough persisted. Although the temperature rose to 103.8 F. the night of the seventh day and he became drowsy, there was suddenly a feeling of relative well-being on the following day, with sudden resolution of fever by crisis and with profuse sweats. He was afebrile by the ninth day, out of bed on the tenth day and back to work on the thirteenth day, although he tired easily on exertion. The blood pressure remained normal throughout, and there was no rash. The lungs were clear.

The leukocyte count on the seventh day was 5,000. On the thirteenth day, a complete examination of the blood at an outpatient clinic showed 4,620,000 red cells, 90 per cent hemoglobin and 6,600 leukocytes, with a differential count of 64 per cent polymorphonuclear leukocytes and 36 per cent lymphocytes. On the twelfth day urinalysis was negative except for a faint trace of albumin, with a few leukocytes in the microscopic examination. These findings had disappeared by the following day. On the twenty-first day the electrocardiographic tracing was normal in all four leads. The heart rate was 84, the PR interval was 0.16 second, there was sinus rhythm, the QRS complexes were 0.06 second, the T waves were upright in all leads and there were no ST changes.

The serologic changes are given in detail in table 3. Briefly, the Weil-Felix reaction became positive on the seventh day with a titer of 1:40 and reached as high as 1:80 by the fourteenth day. The complement fixation began to rise with epidemic antigen by the end of the first week and was still strongly positive by the fourth month. Rickettsial agglutination did not rise until the second week but reached its peak at that time with a titer of 1:640 with epidemic antigen. It was still positive by the fourth month.

Case 4.—A man aged 32, an officer, was engaged in typhus control work in Fischbach, Germany. On March 23, 1945, he and another officer (case 5) were heavily exposed to dust containing suspended louse feces in the room of a barracks (recently taken from the Germans) in which louse-infested Russian typhus patients were hospitalized. A Russian male nurse had just vigorously shaken out a shirt belonging to one of the patients. The officer (case 4) had received only three 1.0 cc. doses of typhus vaccine, given one week apart in April and May, 1944. The first dose was received April 25, 1944 and the last dose May 9, 1944, a full year before exposure to infection.

The onset of illness was April 2, 1945 with headache, chilliness, decided fatigue and mental depression. These symptoms persisted, and the following day the patient had a shaking chill. The next day, the third day of disease, he was admitted to the hospital for an elective surgical operation of minor nature. Although his temperature at this time was 100 F., physical examination revealed no abnormalities. He was closely observed, and on the fourth and fifth days, although his temperature had risen to 103 F. and he had several shaking chills and an increase in headache, backache and generalized malaise, no observations of a diagnostic nature other than cervical adenopathy and pain in the right upper quadrant were evident. In the next six days his temperature ranged from 101 to 104.5 F. and he complained bitterly of an excruciating headache. He was nauseated and vomited. Malaria, meningitis, hepatitis and infectious mononucleosis were considered in the differential diagnosis along with typhus fever, although definite evidence could not be obtained for any of these diseases. Finally, the diagnosis was clarified on the eighth day by the appearance of a crop of pink macules over the abdomen, chest and back. This rash spread to the arms and legs by the following day but began quickly to fade shortly thereafter (on the tenth day) with an abrupt fall in temperature; it disappeared on the twelfth day. There were no hemorrhagic residues. The fever, which fell by crisis, reached normal by the afternoon of the eleventh day. On the fourteenth day the patient was permitted to get out of bed, and convalescence was uneventful except for weakness and depression.

Many diagnostic laboratory procedures, such as blood culture, lumbar puncture, blood smears and various agglutination tests, were performed on this patient in the early acute phase of the disease but were all essentially negative. Roentgenologic examination of the chest on the ninth day revealed clear lung fields. The leukocyte count on the eleventh day was 7,000 with 70 per cent polymorphonuclear neutrophils, 20 per cent small lymphocytes, 8 per cent large lymphocytes and 2 per cent basophils; on the fifteenth day the leukocyte count was 8,000 with an essentially normal differential count. The Proteus OX 19 agglutination titer rose from 1:40 on the eighth day to 1:640 on the seventeenth day. The complement fixation titer for epidemic antigen on the twenty-third day (performed at the First Medical General Laboratory in Paris) was 1:1,024. Almost a year later this reaction was still positive in a dilution of 1:20, while the Weil-Felix reaction was negative.

Case 5.—A man aged 45 was the chief medical officer of a Civil Affairs unit in Germany and frequently came into contact with typhus patients during the course of his work. On March 23, 1945 he was heavily exposed to dust containing suspended louse feces along with and under the same conditions as the officer in case 4. He had received a total of 8.5 cc. of typhus vaccine from August 1942 to Dec. 28, 1944. All these doses were 1.0 cc. except for a single dose of 0.5 cc. On March 22, 1945 he received his final stimulating dose of 1.0 cc. of the vaccine.

The illness of the patient began on April 2, 1945 with fever and headache. These symptoms became progressively severer together with anorexia during the ensuing five days. Finally, when the headache became excruciating in severity and a nonproductive cough set in, he reported on the eighth day to a medical dispensary. His temperature was 103 F. He was not hospitalized but was put to bed in his quarters. The temperature progressively fell during the next several days, becoming normal by the thirteenth day, and the headache abated. He returned to work on the fourteenth day. There were no chills. Cutaneous eruption was absent.

Appropriate laboratory procedures were not performed during the acute stage of the disease to confirm the diagnosis. A specimen of blood collected on the twentieth day and examined by the First Medical General Laboratory revealed a complement fixation with epidemic antigen in a dilution of 1:128 and with murine antigen in a dilution of 1:64. Unfortunately, no record exists of further specimens being examined for serologic data until July 2, 1945. This sample, examined at the Army Medical School in Washington, D. C., indicated that the complement fixation titer had dropped but was still positive in a dilution of 1:40. Complement-fixing antibodies were still present in a titer of 1:20 almost a year after the onset of illness.

CLINICAL FEATURES

The clinical features of the 5 cases reported herein are summarized in table 2. All the patients were male officers; 3 were in their thirties and 2 were in the fifth decade of life. Except in case 4 all patients had received adequate amounts of vaccine and stimulating doses had been administered within eleven to seventy-three days prior to the onset of disease. The officer in case 4 had only an initial series of three 1.0 cc. doses of vaccine, the last dose having been administered almost a full year before the onset of typhus. In this connection it is interesting to note that he not only suffered the severest attack of typhus of any of the group, with asthenia lasting well into late convalescence, but also presented a widespread eruption over the entire trunk, legs and arms. The incubation period ranged from ten to thirteen days in the 3 cases in which it could be accurately determined, was questionable at twelve days in 1 case and was less than seventeen days in another case. Only 2 of the 5 officers were ill enough to be admitted to the hospital; the others remained in bed in their quarters. Of particular interest is the short period for which they were confined to bed. In 3 cases this was five days or less; in the remaining 2 instances it was ten and eleven days, respectively. The duration of fever (less than 99 F.) from the onset of disease was likewise reduced in comparison with that in the average unvaccinated patient, the values being six, ten, nine, eleven and twelve days for cases 1, 2, 3, 4 and 5, respectively. Rash was absent in 2 cases and even when present (except in case 4) was not striking. Symptoms referable to the central nervous system, except for headache, were conspicuous by their absence, although in case 2 the patient was said to have shown some indication of disorientation for a short period. This, however, was never substantiated. Headache was severe in every instance and was by far the most striking symptom of the disease. Leukocyte counts were performed in 3 cases during the course of the disease, early and late. In no instance was there a leukocytosis, thus giving the picture of an uncomplicated rickettsial disease. In classical typhus, early counts not infrequently show a leukopenia while later in the disease with the appearance of bacterial complications the count rises rapidly with an increase in the young neutrophilic fraction of the differential count. There was no evidence in any of the cases of undue prostration or of cardiovascular or renal involvement.

The picture reported here is in decided contrast to that in the unvaccinated patient with classic typhus. The temperature in classic typhus usually remains elevated between 104 and 106 F. until the end of the second week; the patient becomes delirious, comatose and finally stuporous, and signs of cardiovascular and renal involvement may appear. The rash is extensive and hemorrhagic, and convalescence is prolonged.

Of particular interest is the method of infection. In every instance there was considerable evidence to indicate that infection was not sustained by the "bite" of a louse but rather by the inhalation or conjunctival absorption of suspended infected louse feces. It has been well known for many years that physicians and nurses attending patients with epidemic typhus fever contract the disease in spite of active and vigorous measures to prevent infestation with lice.

SEVERITY AND MORTALITY OF POSTVACCINATION TYPHUS

The clinical features of the 5 cases of postvaccination epidemic typhus described here are in general accord with those already described for laboratory [17] and field [18] infections. These studies show that the clinical course of epidemic typhus is greatly modified when infection occurs subsequent to immunization with vaccine. The temperature is much lower and the fever is of shorter duration than in nonvaccinated patients, the period of hospitalization (if necessary) is appreciably reduced, the extent and duration of rash is diminished, circulatory and nervous symptoms are lessened and the incidence of complications is brought down to an exceedingly low figure. The most striking result of immunization, however, is the fact that there has not been a single death reported in the series of cases of adequately vaccinated patients studied in these investigations.

In many instances the diagnosis of typhus is extraordinarily difficult in vaccinated persons because of the modification of the clinical picture and serologic procedures must be employed for confirmation. The only important symptom which regularly remains is the severe headache.

It is difficult at this time to accurately state the time limits within which one may expect satisfactory protection from typhus after vaccination. It would appear, however, from such data as are available that protection is adequate up to a year following vaccination and that there is little indication that vaccine exerts a favorable action unless it is given at least one and a half or two weeks prior to exposure. Ecke and his colleagues [16d] observed that there was no apparent diminution in benefit up to three hundred and twenty-five days subsequent to the reception of a dose of typhus vaccine, and that while the course of illness was somewhat shorter and milder in a group of patients who were vaccinated within one and a half to two weeks prior to the onset of the disease, fatality might occur. A 35 year old man who was vaccinated three days before the onset of disease died with epidemic typhus. In the present report, 1 patient (case 4) had not received vaccine for eleven months prior to the onset of disease. His disease ran a moderately severe course, and he had an extensive rash. In the light of this experience, the time limit for maximum effectiveness of vaccine appears not to exceed six months after the initial series or stimulating dose; and suitable protection cannot be expected unless the vaccine has been administered at least four weeks prior to the onset of disease or two weeks before exposure. In this connection, Topping, Henderson and Bengtson [19] have brought out the importance of the stimulating dose of vaccine in producing a high titer antibody that will persist for a considerable period of time.

SEROLOGIC DIAGNOSIS

The discovery of the Weil-Felix agglutination test, employing suspensions of certain strains of Proteus provided a serologic reaction which was extensively used in the diagnosis of typhus fever. This reaction, although nonspecific, was of great value. Subsequently it became known that this reaction not only failed to differentiate between certain members of the group of rickettsial diseases but also did not differentiate between epidemic and murine typhus. Such distinction is of importance in survey and control work with typhus fever. This differentiation also proved to be desirable in the case of troops who, during the past war, became infected with typhus in many parts of the world.

The successful effort of Cox [8] in cultivating rickettsias in the yolk sac of the fertile hen's egg and Craigie's [10] demonstration of the ether method of extracting such cultures led to the preparation of a rickettsial antigen with which serologic studies (agglutination and complement fixation) could be performed.

Bengtson [20] described a complement fixation test for murine typhus. This complement fixation reaction, as subsequently developed and elaborated, not only clearly differentiated typhus from other rickettsial diseases but also served to separate epidemic from murine typhus provided that certain precautions, as outlined by Plotz, Wertman and Bennett [21] were closely followed. These investigators showed that when the rickettsial suspensions were rendered free of soluble antigen, specific complement-fixing antigens were obtained with which these closely related diseases could be differentiated.

The serologic response in acquired epidemic typhus fever is now well defined and established.[22] The presence of agglutinins in rising titer for the Proteus OX 19 bacillus may be demonstrated between the fourth to thirteenth day, usually about the beginning of the second week. The titer rises during the second week to reach its maximum in early convalescence and usually disappears about three months after onset. Complement-fixing and rickettsial agglutinating antibodies can be demonstrated during the second week of disease.

[22] Plotz, H.: The Significance of the Serological Reactions *in the Diagnosis of* Rickettsial Diseases, in Transactions of the First Inter-American Conference on Typhus Fever, *Mexico City, 1945*, to be published.

Rickettsial agglutination reaches a nonsignificant titer in late convalescence, while the complement-fixing antibody seems to persist for years after an attack. Indeed, Plotz[22] has found complement-fixing antibodies in epidemic and murine typhus in 2 instances as long as thirty-two and twelve years subsequent to the active infection.

Recently the development of serologic response in man after the administration of epidemic typhus vaccine has been studied by Topping, Henderson and Bengtson[19] and Zarafonetis.[23] These studies briefly show that while such vaccination calls forth epidemic complement-fixing antibodies in low titer there is usually little or no response with the Weil-Felix test. While there is an increase in complement fixation titer as a result of booster vaccination, the trend is still for a return to the prebooster level within several months after the booster injection.

When a person who has received typhus vaccine becomes infected with epidemic typhus, the Weil-Felix reaction, rickettsial agglutination and complement-fixing antibodies appear somewhat earlier than in nonvaccinated persons[24] but continue to rise and eventually yield a serologic picture similar to that in the nonvaccinated patient. In general the titer obtained with complement-fixing epidemic antigen exceeds that with murine antigen, but occasionally considerable cross fixation may be observed.[24a] Until further data are obtained it is therefore unwise to depend solely on the complement fixation reaction for differentiation between epidemic and murine typhus in those persons who have been previously vaccinated.

In the patient who contracts murine typhus subsequent to immunization with epidemic typhus vaccine, Plotz and Wertman[25] and Zarafonetis and his co-workers[24a] have found that complement-fixing epidemic antibodies may be evoked in substantial titer, thus rendering differentiation impossible by the complement fixation reaction alone. Such differentiation, according to Plotz and Wertman,[25] can only be achieved by using the specific rickettsial agglutination test.

The serologic reactions[26] in the 5 cases reported here are summarized in table 3. Agglutinins for Proteus OX 19, while generally not present in the preinfection stage, appeared in low titer by the seventh to ninth day. In 2 of the 4 instances in which this test was carried out the titer never exceeded 1:80, while in the remaining patients (cases 2 and 5) the titer reached a peak of 1:1,280 and 1:640 during the third week. The titers dropped rapidly to attain a negative value except in case 5, in which a value of 1:40 was found almost a year following infection.

Complement-fixing antibodies were found in low dilution prior to infection in all 3 instances in which the test was performed. These titers (1:8, 1:8 and 1:10) were due to immunization with vaccine. In case 2, in which tests were carried out daily during the first week of disease, the complement fixation titer rose from 1:8 to 1:32 on the fifth day, 1:64 on the seventh day, 1:128 on the eighth day, 1:256 on the twelfth day and 1:512 on the nineteenth day. This illustrates in excellent fashion the early and rapid rise of complement-fixing antibodies in the previously vaccinated subject. Although the serologic course was not followed as early and as consistently in the remainder of the cases, the results in general show that complement-fixing antibodies were rising rapidly by the end of the first week to reach their peak in the second or third week. Such peak titers ranged between 1:128 to 1:1,280 in the 5 cases studied and fell off slowly in late convalescence. The titer was still positive at 1:10 in case 1 almost two years after infection, at 1:20 in case 2 one and a half years after infection and at 1:20 in cases 4 and 5 a year after infection. In case 3, which has been followed only four months since the onset of disease, the complement fixation titer remains positive in a dilution of 1:320. In all instances the differentiation with epidemic and murine antigens was clearcut.

Although the complement fixation titer obtained in case 5 was never above 1:128, a value which may be observed on occasion with vaccination alone, the diagnosis of epidemic typhus seems valid on the basis of the persistence of such antibodies for a prolonged period and the clinical history of exposure and onset of disease identical with that in case 4.

It was possible to obtain data on specific rickettsial agglutination throughout the course of disease only in case 3. Here the appearance and rise in titer roughly paralleled that of the Weil-Felix reaction, although higher values were obtained and agglutinins persisted for a longer time. In case 2, in which the test was performed almost two years after infection, and in cases 4 and 5, in which the test was carried out one year subsequent to the active attack of disease, the values obtained were negative.

The above results are consistent with those already recorded in the literature and confirm the usefulness of the complement fixation reaction and rickettsial agglutination test in the diagnosis of typhus following vaccination. They also demonstrate that although the Weil-Felix reaction may prove useful in such confirmation the titers usually obtained are low, and conclusions must be based on a series of examinations rather than on one or two tests.

SUMMARY

In the period Jan. 1, 1942 to Dec. 31, 1945 there were reported in the entire United States Army 64 cases of epidemic typhus, 603 cases of murine typhus and 6,685 cases of tsutsugamushi fever, or scrub typhus. There were no deaths during this period from epidemic typhus fever.

While no conclusions can be drawn concerning a reduction in the incidence of epidemic typhus by prophylactic immunization with Cox type ether-extracted typhus vaccine, it appears definite that such vaccination does serve to greatly modify the disease if it occurs in an adequately vaccinated person and does render the chance of death from typhus practically nil.

The clinical records and serologic observations in 5 cases of epidemic typhus fever occurring subsequent to prophylactic immunization are reported. In all 5 cases it was highly probable that infection was sustained by pulmonary inhalation or conjunctival absorption of dust which contained infected louse feces.

Complement-fixing antibodies for epidemic typhus persisted for prolonged periods of time, while the Weil-Felix reaction and the specific rickettsial agglutination became negative in late convalescence.

THE VALUE OF ENDOTRACHEAL INTUBATION

RICHARD FOREGGER, M.D.
Milwaukee

In a previous article[1] I described a method for the removal of accumulated tracheal secretions by suction through an endotracheal tube over a long period of time. I showed that this is a life-saving measure and can often be used when bronchoscopy is impossible and tracheotomy is not feasible. I have now succeeded in accumulating further cases to demonstrate the life-saving nature of intubation, apart from its already familiar use during anesthesia. These are cases which came to my attention during the recent war, but the conditions, the treatment and the lessons learned will apply as well to civilian life. Anesthesia, asphyxia, trauma of the respiratory system and trauma to the central nervous system resulting in unconsciousness, concussion or paralysis all give rise to weakness of the respiratory musculature and depression of ciliary activity. Obtundation of the cough reflex and depression of ciliary activity, which are the normal cleansing mechanisms of the lung, soon result in the accumulation of tracheobronchial secretions. These must be removed. I am concerned in this paper with severely wounded men whose normal pulmonary protective functions are depressed, not with the patient who can effect this cleansing by himself if he is encouraged to change his position and to cough. To date four methods for tracheobronchial drainage in the depressed or weakened person have been described. They are as follows:

1. The single catheter method, in which endotracheal aspiration is accomplished by the use of a no. 16 French soft rubber urethral catheter. It has been fully described elsewhere.[2] During the course of the aspiration should the vocal cords close around the narrow catheter the airway will become blocked. If suction is continued, collapse of the lung could occur. The proponent of this method uses it only when equipment is not available for other methods, and he warns that "unless intermittently applied, the suction will provoke severe coughing and cyanosis, and accordingly, the suction should be used for periods of only several seconds each, the patient being allowed to take a few deep breaths between each period of suction."[2b]
2. Suction with a small catheter through a wide bore endotracheal tube. This is the method which is now termed tracheobronchial toilet in the official nomenclature of the American Society of Anesthesiologists. It was described by Franz Kühn of Cassel, Germany, in 1912.[3] Kühn advocated the use of the wide bore tube in the trachea, because it acted as a speculum preventing glottic spasm and the resultant damage of lung collapse as mentioned heretofore. It thus assures a good airway while suction is being applied by means of the small catheter. Various technics embodying the essential principle of Kühn's method have been described in the intervening years.[4]
3. Suction through a bronchoscope.
4. Suction through tracheotomy.

Having these four potent weapons to combat the accumulation of pulmonary secretions, the physician employs whichever is best suited to the case in hand.

REPORT OF CASES

Case 1.—L. Q., aged 25, received a penetrating wound of the right side of the chest with a sucking pneumothorax on July 19, 1944 near Périers, France. He was given ½ grain (0.03 Gm.) morphine on the battlefield and 2 units of plasma at the collecting station. Anesthesia was commenced at 45 minutes past 3 o'clock and intubation was performed. There was blood in the trachea. The thoracic wounds were debrided and closed. In the evening immense emphysema of the face, neck and thorax with severe respiratory distress developed in the patient. Blind intubation was performed through the right nostril with considerable relief of the respiratory distress. Cutaneous incisions were also made to relieve the pressure. The next day the emphysema continued, and suction was performed at intervals to remove tracheobronchial secretions. On the second day at 45 minutes past 2 o'clock the tube was removed, as the emphysema had subsided enough that obstruction no longer existed. The patient could cough efficiently and coughed up some frothy blood-tinged mucus during the rest of the day. He also had a whispered voice and a slightly sore throat, but the airway was clear. During the next few days the whispered voice persisted, and he continued to cough up bloody mucus. On the sixth day his voice returned, but it was hoarse. I examined his larynx and could see no edema, hemorrhage or hematoma, but there was hyperemia. On the tenth day his speech was normal. Most of the intense emphysema had by now subsided. To summarize, the tube was left in place for forty-one hours. There was dysfunction and hyperemia of the organ of speech for eight days. Thereafter his speech was normal.

Case 2.—L. L., aged 21, on June 24, 1944 during the drive to Cherbourg, France, sustained a puncture wound of the left side of the chest posteriorly with indications of massive hemorrhage inside the thorax. Sixteen hundred cubic centimeters of blood had been withdrawn from his chest by paracentesis, but because of continued respiratory distress and cyanosis the surgeon contemplated a thoracotomy to ligate a bleeding intrathoracic vessel. While the surgeons were preparing to operate I passed a no. 10 Magill tube through the right nostril blindly into the trachea of the conscious patient. After the removal of large amounts of bloody mucous secretions, the patient's condition improved until he was able to aspirate his own trachea. It was apparent that his respiratory difficulty was solely due to accumulated tracheobronchial secretions and not due to compression by a mass of blood, i. e., there was no bleeding intrathoracic vessel. Surgical intervention was deferred, and recovery was uneventful.

Case 3.—M. D., aged 25, received a gunshot wound of the left cheek near Mortain, France, on Aug. 11, 1944. The bullet had perforated the left cheek at the level of the second upper molar and had lacerated the tongue, but it could not be determined exactly where the bullet lodged. The patient was conscious and could speak. He was given a solution of ⅛ grain (0.008 Gm.) morphine and 1/100 grain (0.0006 Gm.) atropine subcutaneously. The nose was cocainized. Right blind nasal intubation was performed with ease, and he was anesthetized with pentothal sodium, nitrous oxide, oxygen and ether. The throat was packed. The wounds were debrided, fragments of bone were removed and, after much probing and pulling at what was thought to be the bullet, the surgical operation was ended without removing the bullet. After the operation the patient did not respond as was anticipated, despite the fact that anesthesia had been light. The mandible was relaxed, and there was no response to nociceptive stimuli. The endotracheal tube was left in place. When I saw him two hours after the operation the pharynx was full of blood, and blood was coming out of the tracheal tube with each respiration. The patient's breathing was obstructed and he was hypoxic. His blood pressure was 80 systolic and 20 diastolic, his pulse rate was 140, and his condition was adjudged critical. Suction through

the endotracheal tube resulted in much improvement within fifteen minutes. Throughout the night suction and oxygen were employed.

The next day examination of the spinal fluid and the eye grounds revealed the presence of a basilar fracture of the skull. He remained unconscious, but the chest remained clear to auscultation.

On the second day the tracheal tube was still in place. He was rapidly regaining consciousness. He was restless and responded to nociceptive impulses, although the sensorium was still somewhat clouded. At 10 p. m. the endotracheal tube was withdrawn, since during the day he had improved and had become conscious and cooperative enough to cough up any tracheal secretions. The tube had been in forty-eight hours. The next day he required suction of the hypopharynx only once, and from this time on he was able to cough well enough to clear the tracheobronchial tree of secretions. When I saw him on the fourth day he was talking, and there was no hoarseness. He was alert but not yet sitting up. I examined his larynx. It was normal in every respect.

Case 4.—J. M., aged 35, was wounded Dec. 12, 1944 near Eschweiler, Germany. The patient had a perforating wound of the upper lip and the tongue and was bleeding into the throat. When I arrived the ward surgeon was sucking out the throat and trying to suture the tongue. The patient's color was gray and he was gasping. Right blind nasal intubation was quickly performed, and a large amount of blood was sucked from the trachea. His respiratory rate and his color improved. Suction was continued, and a pack was placed in the hypopharynx and mouth around the endotracheal tube. This served to compress the lacerated tongue and to prevent more blood from going down into the trachea. This patient was operated on several hours later, at which time the left external carotid artery was ligated and the tongue sutured. Recovery from then on was satisfactory.

Case 5.—R. C., aged 19, had been wounded in the neck by a bullet several weeks before I saw him Jan. 21, 1945. At that time he had a fracture of the first dorsal vertebra with traumatic myelitis below this level. Because of weakness of the thoracic muscles he was unable to cough and expectorate, and partial pulmonary atelectasis had developed. A Magill no. 10 endotracheal tube was passed, using cocaine analgesia, and tracheobronchial suction was performed with a urethral catheter passed through the endotracheal tube. Considerable clinical improvement followed immediately, although follow-up roentgenologic examination showed no change in the pulmonary picture. Tracheobronchial aspiration was performed using the same technic six times in the next seven days, each time with distinct clinical improvement. Nightly refilling of the bronchial tree was the indication for the repetition of the procedure. Transoral tracheal intubation was difficult and was accompanied by considerable discomfort to the patient because of his neck wound. Therefore it was thought best to perform tracheotomy, which would permit more frequent tracheobronchial aspirations, and this was done. Following this the atelectasis cleared in a few days, and the condition of the patient improved enough for him to be sent back to America.

Case 6.—Mr. H., aged 65, a British civilian, was hit by a large United States Army truck and sustained fractures of the left femur and the pelvis and a blow in the left frontotemporal region. I saw him Nov. 18, 1943, two days after injury, at which time coarse bubbling rales could be heard from the doorway. He was sitting up in bed with a great deal of respiratory distress evidenced by rapid, labored breathing, retraction at the sternal notch, dilated neck veins and activity of the accessory respiratory muscles. He was moderately confused and aphasic. I performed blind nasotracheal intubation without cocainization five times in the course of the day, through alternate nostrils. There was little if any improvement, so in the evening I decided to leave the tube in place. Secretions were aspirated through this tube over a period of sixty hours. It was here that I learned an important lesson, because not until forty-eight hours had passed did I realize that these aspirations had been carried out too infrequently and in a desultory manner; it was only after the suction had become more vigorous and frequent in nature that decided improvement occurred. The temperature, which had been 103 F., was now normal. The character of the pulse and the respirations was greatly improved. I withdrew the tube, and throughout the day he coughed up copious amounts of sputum from the lungs. He was aphonic for one day, but the airway was free. The next day he was so much improved that the surgeons inserted a pin through the distal end of the femur. He continued well for two days with a normal temperature and a pulse rate below 100. At this time I myself was confined to bed with an infection of the respiratory tract. There was no one to skillfully aid and encourage him in the pulmonary toilet, and he again began to accumulate tracheal secretions. After a few days he died. Autopsy was not performed; neither was the glottis and trachea examined in death by laryngoscopy.

COMMENT

The value of endotracheal intubation as a dramatic life-saving procedure in the unanesthetized person is again herein clearly shown. Moreover, further evidence is offered that the human larynx will withstand repeated intubation, and that a tube may be left in place for a long time without permanent harmful results. There is nothing new in these observations, for William MacEwen of Glasgow recorded in 1880 that he had saved several patients from death by asphyxiation by using an endotracheal tube to provide the necessary airway. In one case he kept the tube in the trachea thirty-six hours and in another, thirty-five hours.[5] But it seems that in medical science the value of some procedures must be repeatedly affirmed before they become part of the physician's daily armamentarium. Although these are all instances arising in military life, the same situations could and do occur in civilian life. Automobile accidents result in trauma to the central nervous and respiratory systems. Brain tumors, infections, poliomyelitis, asphyxia and drug depression all give rise to weakness of respiratory musculature and depressed cough activity. To combat the evil effects of these accidents and diseases of vital functions, skilled physicians and adequate equipment should be as abundant in civilian life as they were directly behind the frontline of battle. It is not asking too much that every medical student should understand the nature of this problem and should begin his training in the art of endotracheal intubation before graduation. In most of the cases cited here, the method of tracheal aspiration using suction through a soft rubber Magill tube was used. But this, although a simple method, does not mean that other methods cannot and should not be used. The important point, in my opinion, is to recognize the nature of the malady and to institute some form of therapy to remove the offending secretions from the tracheobronchial tree. This may be any one of the four known methods for drainage of the trachea, the choice being dictated by the nature of the case in hand and the capacity of the physician whose lot it is to perform the task. Skill in one form may be predominant, and the physician will naturally elect to use the method with which he is most familiar. Skill and dexterity should have their sanction: the privilege to make decisions and perform technics with a tranquil mind and without interference.

CONCLUSIONS

1. Endotracheal intubation is herein shown to be a life-saving measure.

2. The human larynx withstood an indwelling catheter for forty-one and forty-eight hours, respectively in 2 cases, without permanently harmful results.

ESOPHAGEAL LEIOMYOMA

Report of a Successful Resection

PAUL W. SCHAFER, M.D.
and
C. FREDERICK KITTLE, M.D.
Chicago

Benign tumors of the esophagus are rare and usually are encountered as incidental findings at autopsy. Moersch and Harrington [1] have stated that of 11,000 patients complaining of dysphagia only 15 had benign esophageal tumors as a basis for their complaint. In a review of 7,459 necropsies they observed 44 of these tumors. In 6,001 postmortem examinations at the University of Chicago 11 benign esophageal tumors have been found. Case reports and reviews concerning approximately 200 such tumors have been published.[2] A wide variety of benign neoplasms occur in the esophagus: adenoma,[3] papilloma,[4] polyp,[5] fibroma,[6] myxofibroma,[7] neurofibroma,[8] hemangioma,[9] lipoma,[10] ostechondroma [11] and the most frequent form, myoma.[12]

There have been few reports on the surgical treatment of benign esophageal tumors. This is due not only to the paucity of these lesions but also to the relatively recent advance of surgery to a stage where intervention is advisable. Three cases of surgical resection of esophageal myoma have been published, of which only 1 was successful. This was described in Ohsawa's remarkable discussion in 1933.[13] He described a 43 year old woman who had experienced dysphagia for twenty-four years. A diagnosis of idiopathic esophageal dilatation was made. In performing an esophagocardioplasty for relief of the cardiospasm, Ohsawa encountered an unsuspected submucosal myoma about 1 cm. in diameter, which he enucleated.

Another case was reported by Harrington and Moersch.[14] Their patient was a 39 year old man, who gave a history of asthmatic bronchitis and hay fever of twenty years' duration. No dysphagia or regurgitation had occurred. Roentgen examination revealed an increased density in the left side of the inferior posterior mediastinum. The lower end of the esophagus was deformed and displaced to the left. These observations suggested a diaphragmatic hernia. Endoscopic examination showed that the esophagus was irritated by regurgitated gastric juice and confirmed the deflection previously noted. Through a left transpleural route, the esophagus was visualized and its lower 5 inches (12.7 cm.) found to be surrounded by a lobulated tumor mass which extended to the cardia. The lower fourth of the esophagus, the major portion of the tumor and the cardia were resected, and an esophagogastrostomy was performed. The patient expired on the fourth day after the operation from bilateral bronchopneumonia. These authors [14] described another myoma which occurred in a 56 year old woman, but since it was located at the cardioesophageal junction it was impossible to state definitely that it was of esophageal origin.

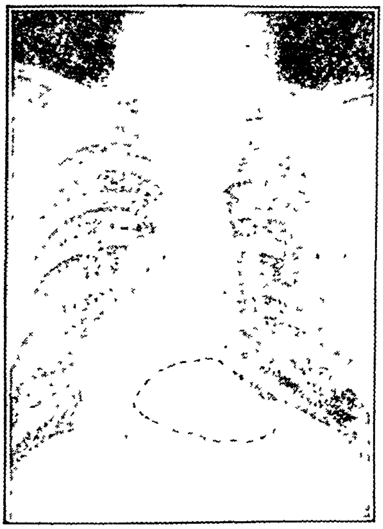

Fig. 1.—Roentgenogram of the chest showing the leiomyoma as a rounded mass of increased density in the right inferior mediastinum.

Also a large cardioesophageal myoma has been successfully resected by Brock.[15]

Harper and Tiscenco [16] mention the case of a 41 year old man who for three years had experienced tightness and distention in his epigastrium shortly after eating. This was of an intermittent nature and was alleviated by vomiting. Occasionally a choking sensation was present. Because of these symptoms he was placed on ulcer management, which failed to bring relief. Esophagoscopy showed a mucosa-covered tumor in the right lateral wall of the esophagus 30 cm. from the incisor teeth. A filling defect in the lower half of the esophagus without obstruction was apparent at roentgen examination. At operation Dick [17] encountered a mass on the posterolateral wall of the esophagus extending upward posterior to the aortic arch. Histologically the resected tumor was a leiomyoma. The patient succumbed on the fourth day, and at postmortem examination bilateral "wet lungs" were found.

Recently a large leiomyoma of the lower thoracic esophagus was successfully resected at the University of Chicago Clinics. A detailed report of this case seems of value.

From the Department of Surgery of the University of Chicago.

REPORT OF A CASE

A 46 year old Polish laborer presented himself at the University of Chicago Clinics Jan. 22, 1946. He was seen first in the emergency clinic with complaints of epigastric distress and pain in both costovertebral angles. Although this had been continuous for six weeks it had been especially severe for only two days. Closer inquiry revealed that for eighteen months he had noticed occasional pain in the lower part of his chest on the right side. His family physician considered this due to pleurisy and applied adhesive strapping to his chest. This brought relief for several months, after which the pain recurred and persisted with exacerbations and remissions until his admission. Several of the acute episodes of pain were accompanied by nausea, vomiting and frontal headaches. He had experienced some anorexia and had lost 14 pounds (6.4 Kg.). At no time had dysphagia been present. Inquiry by system and history were not contributory. There was decided tenderness in both costovertebral angles, but the remainder of the physical examination revealed no abnormalities. Hemoglobin determination, red and white blood cell counts and routine urinalysis were within normal limits. The blood Wassermann test was negative. Stereoroentgenograms of the thorax revealed a large, rounded mass of increased density in the lower posterior mediastinum, suggestive of a diaphragmatic hernia (fig 1). Fluoroscopy during a barium swallow showed the lower part of the thoracic esophagus to be displaced to the right, the position of the esophagus corresponding to the right margin of the previously noted mass (fig. 2). Approximately the upper fifth of the stomach lay within the mediastinum, but it seemed to be insufficient in volume to have displaced the esophagus so widely. Barium studies of the small intestine and large intestine were done with the thought that possibly these structures also might have passed through the diaphragmatic defect. This was not found to be the case. Intramural or extrinsic tumor was not considered likely. A diagnosis of eccentric diaphragmatic hernia was made and operative intervention advised.

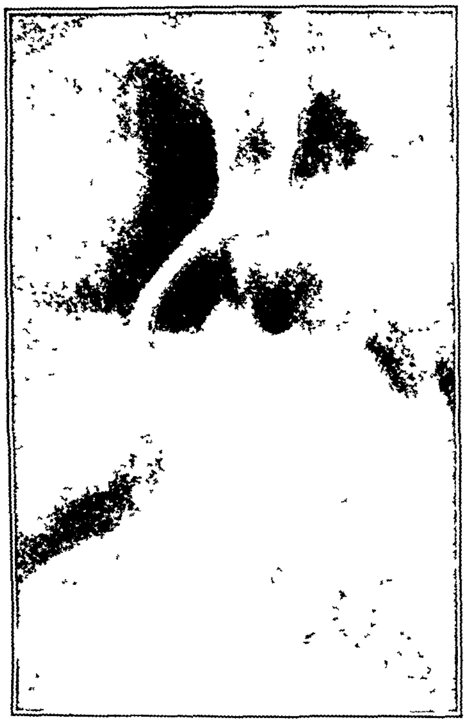

Fig 2—Lower esophagus and stomach during ingestion of a barium meal The lower esophagus is compressed and deviated while the upper fifth of the stomach lies above the diaphragm

On Feb. 23, 1946 under positive pressure, ethylene-oxygen anesthesia the left pleural cavity was entered through the bed of the resected ninth rib. A more adequate exposure was obtained by removal of 2 cm. segments of the posterior parts of the eighth and seventh ribs, with division of the intervening intercostal structures The left lung was retracted superiorly after division of the pulmonary ligament. Palpation of the mediastinum revealed a large, firm mass in the region of the lower esophagus. The mediastinal pleura was incised and the mediastinal cavity explored. The esophageal hiatus was found to be enlarged to a diameter of 5 cm., and the greater part of the fundus of the stomach protruded through this opening. The diaphragm was opened obliquely along its anterolateral aspect and the liver, kidney and spleen identified in their normal locations. It was obvious from this that the palpable mass was a tumor and not a visceral herniation. The stomach was replaced into the abdominal cavity, the diaphragm repaired by use of a continuous suture of doubled 0 chromic catgut, and the hiatus reconstructed to a diameter of 2 cm. The lower esophagus together with the mass was delivered into the operative field. The tumor measured 7 by 7 by 10 cm. and partially surr

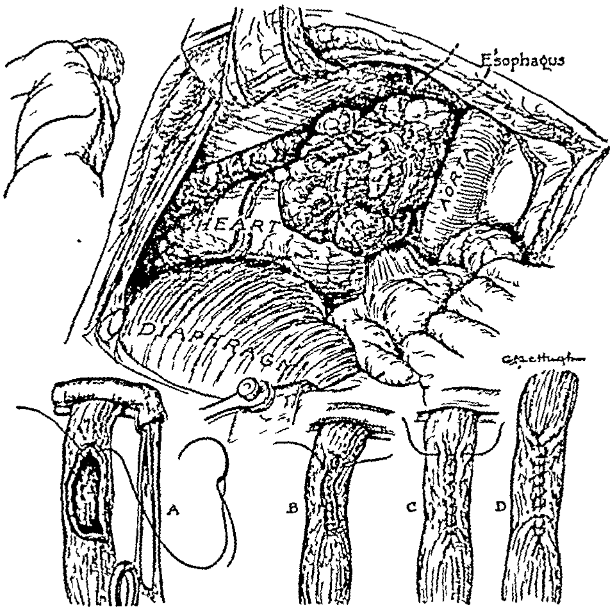

Fig 3.—Operative sketch showing the location and relationships of the tumor and the hernia as well as the incision and method of repair

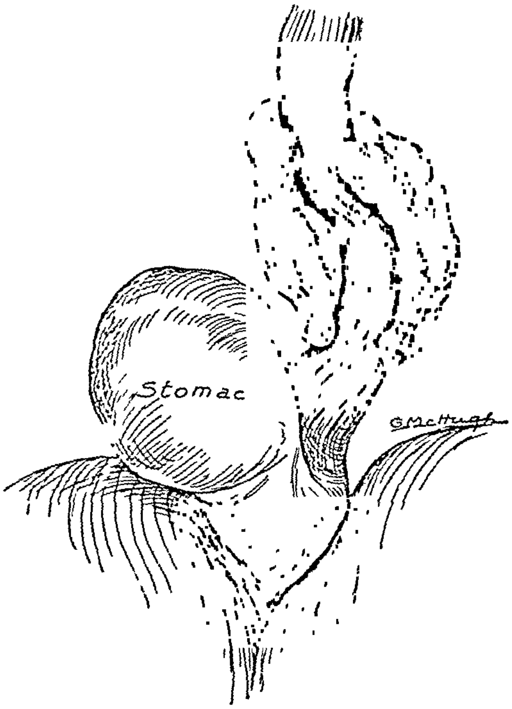

Fig 4—Posterior view of the tumor and herniated stomach.

the lower part of the esophagus. It took its origin from the left posterolateral wall of the esophagus 6 cm. above the diaphragm. The tumor mass was irregularly lobulated, firm, and sharply delineated from the surrounding tissues (figs. 3 and 4). Microscopic examination of a frozen section revealed it to be a leiomyoma. Because of its origin in the wall of the esophagus, it was necessary to excise an ovoid portion of the left posterolateral wall measuring 3 by 7 cm. This defect was closed longitudinally by two rows of interrupted 0 chromic catgut sutures. A de Pezzer catheter was placed in the pleural cavity through a stab wound in the tenth interspace. The wall of the chest was closed in anatomic layers, and the lung was reinflated. While the operation was being performed the patient received 1,200 cc. of whole blood and 1,500 cc. of isotonic solution of sodium chloride intravenously.

Intranasal oxygen was given for two days after the operative intervention. The administration of oral fluids was begun on the fifth day. Other than a slight amount of pain along the external operative site the patient had no complaints, and his postoperative course was uneventful. He was discharged from the hospital on the thirteenth day after the operation.

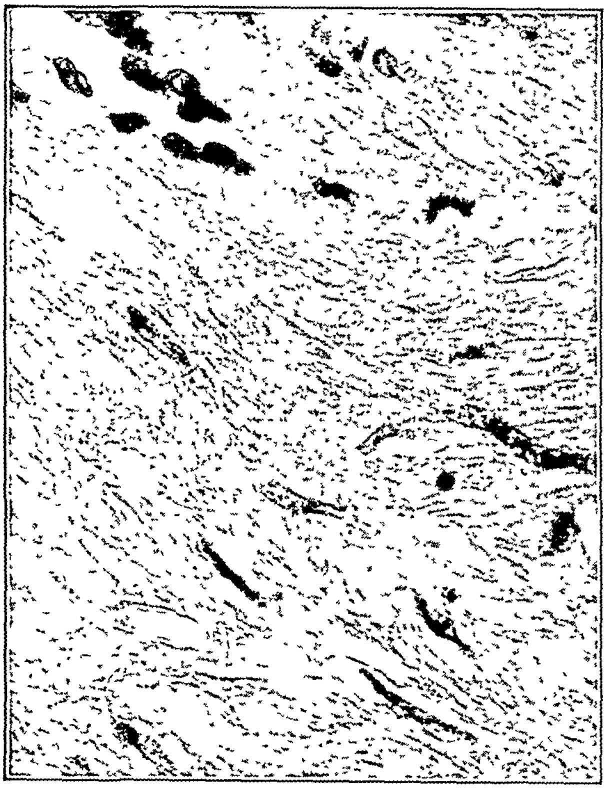

Fig 5—Photomicrograph of the tumor showing strands of smooth muscle cells about the hyalinized vessel.

Roentgenologic examination of his chest and fluoroscopy during a barium swallow one month after the discharge of the patient showed a slight deviation of the esophagus to the right in its lower part but no recurrence of herniation. The patient has had no complaints or evidence of former symptoms since discharge, and when last seen July 1 he was anticipating his early return to hard labor.

The pathologic specimen consisted of an ovoid mass of nodular, firm tissue, which measured approximately 7 by 7 by 10 cm. and weighed 178 Gm. On one side was a deep groove through which the esophagus had coursed, and attached here was a 3 by 7 cm ovoid piece of esophageal wall, from which the tumor appeared to originate. On cut section the tissue was uniformly firm, and many small cystic areas, none larger than 1 mm., were present.

Microscopically the tumor was composed of smooth muscle cells arranged in strands and whorls separated by septums and bundles of connective tissue (fig. 5). The relative amounts of connective tissue and muscle fibers varied greatly and were similar to the variability present in uterine leiofibromyomas. In those areas in which the collagenous tissue predominated the muscle cells were sparse and atrophic. Where the muscle fibers were more abundant, their cells were large and vacuolated. In no place was there any suggestion of cross striation of the muscle fibers. The configuration of the muscular and connective tissue suggested a multilobular appearance, as though there were multiple centers of growth. Phosphotungstic acid and hematoxylin stains identified myofibrils in spindle-shaped cells coursing among connective tissue strands.

The tumor was sharply demarcated from peripheral fatty and areolar tissues, but no distinct capsule was present. The entire tissue contained numerous poorly developed, endothelium-lined cavities, some of which contained red blood cells, while others held a clear fluid or were empty. The majority of these vascular spaces had a dense hyaline wall. In many instances hyaline thrombi were present, and not infrequently the vessel was completely obliterated. Often the spaces were compressed to mere slitlike channels. Focal areas of fatty, hyaline and, infrequently, calcific regression were present, especially near the thrombosed and densely hyalinized vessels.

There was an occasional perivascular focus of lymphocytic infiltration. In some instances these accumulations resembled lymph follicles. In other places this invasion was more diffuse and consisted of a mixture of eosinophils and lymphocytes.

No nerve fibers or ganglion cells were seen in any of the sections

COMMENT

Benign tumors of the esophagus can be divided into two general types, depending on whether they originate from the mucosa and submucosa or from the muscularis. This is a distinction applicable not only to the histologic type but to the clinical symptomatology as well. While the papillomas, adenomas, myxofibromas, lipomas and hemangiomas arise from the submucosal area, the most commonly observed type, the myoma, originates from the muscular coats of the esophagus. The submucosal neoplasms grow into the lumen of the esophagus, usually becoming pedunculated as a consequence of the continued deglutitive process, and produce dysphagia because of their bulk. These are the spectacular patients who present themselves with a tumor hanging from between their teeth. A history of vomiting forth and then swallowing a long pedunculated mass may be given.

Myomas and other intramural tumors produce symptoms by their expansile growth into the adjacent structures. Epigastric or retrosternal distress, intermittent dyspnea and cough are the most commonly reported symptoms. Seldom does dysphagia occur.

Although myomas of the alimentary tract are frequent at necropsy, they appear least often in the esophagus.[18] There they are usually small and have little, if any, clinical significance. Rose [19] in a review of 49 autopsies found the tumor multiple in 11 of 46 instances and commonest in the distal third of the esophagus. In only 4 of his cases did the myomas produce symptoms. Their size varies from a few millimeters to several centimeters in diameter. Stewart [20] discussed 2 cases in which the tumors were associated with diverticula, a situation previously noted by Monro.[20] Myomas of the esophagus seldom involve its entire circumference and only produce symptoms when they attain large size or become malignant. That this last possibility is unlikely is suggested by French and Garland and others [21] who have reviewed sarcomas of the esophagus.

[21] French, L. R., and Garland, L. H.: Leiomyosarcoma of the Esophagus, Am J. Roentgenol. **45**: 27-31, 1941.

Myomas can arise from either of the muscular layers of the esophagus although more begin in the longitudinal layer according to Rose. Histologically, leiomyomas, rhabdomyomas[22] or tumors composed of both smooth and striated muscle fibers are found. Pichler[23] has described an esophagus containing multiple leiomyomas which included striated muscle fibers and ganglion cells. These tumors undergo hydropic, fatty and hyaline degenerative changes, and calcification often occurs after such regression. The blood vessels are scanty and small, frequently exhibiting obliterative processes. Lymph vessels are fairly numerous and may contribute largely to the nutrition of these tumors. Lymph follicles and round cell infiltration are often present, but the inflammation is usually slight.

Abrikissoff[24] described a special variety of striated muscle neoplasm in 1926 which he designated as a myoblastoma. This tumor is composed of primitive myoblasts, and several have been found in the esophagus.[25]

It should be emphasized that dysphagia is seldom a symptom of esophageal myoma. Dysphagia when present, unlike that associated with carcinoma, is rarely progressive to the point of complete obstruction but remains intermittent and usually slight. Since myomas are most frequently located in the posterior mediastinal space their growth causes few symptoms, and those which do result are not pathognomonic. The presence of a myoma should be suspected when indefinite esophageal or intrathoracic complaints are coupled with a posterior mediastinal mass. Symptoms are of variable duration ranging from a few months to several years. It is of interest that of the 4 esophageal myomas which have been treated surgically the correct diagnosis was made preoperatively in only 1 instance (Harper and Tiscenco[16]), and here the myoma was not associated with any other esophageal lesion. Ohsawa encountered his tumor unexpectedly during the course of an esophagocardioplasty for the treatment of cardiospasm of long duration. In the case of Harrington and Moersch and in the case reported here, a diaphragmatic hernia was considered the most likely diagnosis and was found in the latter instance. From a study of the anatomic relations of the tumor it seems likely that development of the leiomyoma preceded the formation of the hernia, which probably was secondary to traction exerted by the expanding tumor mass.

By far the most useful diagnostic procedure in this condition are stereoroentgenograms of the chest with appropriate oblique views and fluoroscopy during the ingestion of barium. The last allows an accurate evaluation of the position of the tumor. Extensive radiologic discussions of benign esophageal tumors have been written.[26] Esophagoscopy further aids in their localization and permits differentiation of some benign or malignant lesions, particularly when an adequate biopsy can be secured. Bronchoscopy is indicated if the tumor is so located that the trachea or bronchi are displaced.

CONCLUSION

Benign esophageal tumors have been discussed, with special reference to their surgical treatment. The first successful resection of a large intramural leiomyoma of the esophagus to be recorded in the literature has been performed.

Clinical Notes, Suggestions and New Instruments

PENICILLIN THERAPY OF GONOCOCCIC ENDOCARDITIS OF THE PULMONARY VALVE

WALTER K. MYERS, M.D.
Washington, D. C.

In the past gonococcic endocarditis has been of interest primarily as a diagnostic problem. The mortality rate in acute endocarditis due to the gonococcus approached 100 per cent. With the advent of the sulfonamide drugs and the antibiotics, the treatment of gonococcic endocarditis is not without hope. The National Research Council received reports of penicillin therapy in 5 cases of acute gonococcic endocarditis. Recoveries or clinical arrests were reported in 3 of these cases.[1]

REPORT OF A CASE

A Negro girl aged 18 was admitted to the hospital on March 21, 1945. Her chief complaints were pain in the lower part of the abdomen and constant headache of one week's duration, and vomiting for one day.

The present illness began two weeks earlier, at which time she first noted weakness, listlessness and easy fatigability. She had been seen by a local physician because of delayed menstruation. With the onset of her menstruation one week before admission, she began to suffer pain in the lower part of the abdomen which increased in severity and which persisted. She had had for a week before entry a thick white vaginal discharge. For three days before entry she had chills and fever associated with nausea. On the day of admission she had vomited on several occasions. Her family observed that her eyes were yellow.

Her past history was noncontributory except that she had had measles and mumps as a child. There had been a normal pregnancy with delivery of a healthy child nine months before the present illness. Her family history was entirely negative.

The physical examination on admission revealed a temperature of 101 F., a pulse rate of 90 per minute, a respiratory rate of 18 per minute and a blood pressure of 100 mm. of mercury systolic and 70 mm. of mercury diastolic. She was a well developed and well nourished Negress, who was obviously ill and uncomfortable. The mucous membranes were pale and the scleras were decidedly icteric. The heart was of normal size and shape on percussion; heart sounds were of good quality. The second sound over the aortic area was equal in intensity to the second sound over the pulmonic area. There were no thrills; no murmurs were noted. Examination of the abdomen revealed definite tenderness in the right upper quadrant and pronounced tenderness deep in both lower quadrants. No masses or viscera were palpable. Pelvic examination disclosed tenderness in both fornices with pain on movement of the cervix. The fundus of the uterus was of normal size, shape and position. There was a thick white discharge from the cervix. The remainder of the examination was noncontributory.

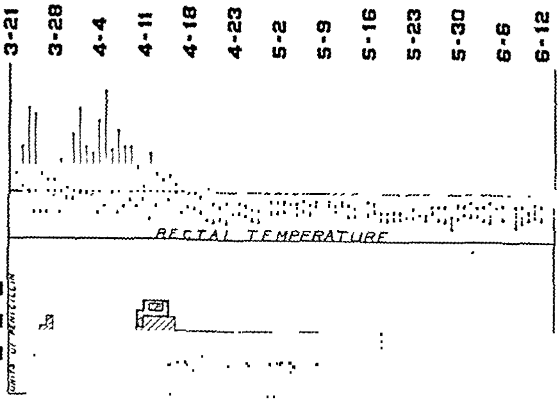
Laboratory studies on admission revealed the following: the blood had a hemoglobin level of 10.5 Gm. per hundred cubic centimeters; 3,610,000 erythrocytes and 30,300 leukocytes per cubic millimeter, with 96 per cent polymorphonuclear cells. The icterus index was 72 units; the van den Bergh reaction was direct, immediately positive with a total of 12 mg. per hundred cubic centimeters. The Kahn and Kolmer tests were negative. Smear and culture of vaginal secretions were positive for gram-negative intracellular diplococci. Examinations of the blood for *leptospira, sickle cells* and erythrocyte fragility were negative. Three blood cultures in the first ten days after admission remained sterile.

The patient remained quite ill. The rectal temperature ranged between 99 and 107.4 F. It was noted that the patient had occasionally only one and frequently two peaks of temperature daily. She received a high carbohydrate diet, dextrose solution intravenously and penicillin intramuscularly, in the dosage of 30,000 units every three hours for a total of 690,000 units over a period of three days. With penicillin therapy there was a subsidence of genital signs and symptoms. The diagnosis at this time was catarrhal jaundice and acute pelvic inflammatory disease due to the gonococcus.

One week after admission, a roentgenogram of the chest revealed a diffuse infiltration of both lungs with a thickened pleura at the right base; a question was raised of a small amount of fluid being present. Temperature ranged between 98 and 101 F. On March 31, ten days after admission, the hemoglobin had fallen to 5.5 Gm. per hundred cubic centimeters; the erythrocyte count was 2,100,000 and the leukocyte count 21,400, per cubic millimeter, with 86 per cent polymorphonuclear cells. The icterus index was 23 units.



Penicillin therapy of gonococcic endocarditis of the pulmonary valve.

On April 1st, eleven days after admission, the patient had a chill and subsequently a temperature of 105.8 F. She was short of breath and complained of moderately severe pleural pain in the right side of the chest. There was a prominent systolic murmur heard to the left of the sternum in the second interspace, which did not radiate. This was accompanied by an unmistakable systolic thrill in the same area. The signs over the pulmonary field were those of flatness, diminished breath sounds and diminished voice sounds over the right base posteriorly and in the axilla consistent with a pleural effusion. The diagnosis suggested was that of an acute endocarditis of the pulmonary valve due to the gonococcus, with associated pulmonary infarction. Blood cultures taken daily from April 1 to 17 inclusive, were reported sterile. Transfusions of 500 cc. of citrated blood were given daily from April 2 to 5 inclusive. A roentgenogram of the chest on April 3 disclosed a diffuse infiltration of the lower half of the right lung. Examination of a sample of sputum revealed no pneumococci or acid-fast bacilli. Diagnostic thoracocenteses were performed April 4 and 6, at which times 26 cc. and 100 cc., respectively, of bloody fluid were obtained. Cultures of both these fluids revealed gram-negative diplococci.

Penicillin therapy was resumed on April 6. The patient received 30,000 units of the antibiotic intramuscularly every four hours for three days, after which the interval was decreased to every three hours. This dosage of penicillin was continued until May 17, a total of 9,780,000 units. Penicillin was also instilled in the pleural cavity in doses of 50,000 units daily from April 10 to 14 inclusive, a total of 250,000 units. On April 12, 13 and 14 no fluid was obtained from the pleural cavity. A roentgenogram of the chest on April 13 revealed only a minor degree of thickening of the pleura at the right costophrenic angle; the pulmonary fields were clear, and there was no evidence of fluid. After April 21 the patient was free of symptoms and the temperature failed to rise above 99 F. (rectally). The thrill over the base of the heart had disappeared, and the systolic murmur previously heard was softer and much less pronounced. On May 1 the administration of ferrous sulfate, 30 grains (2 Gm.) daily, was started. No other therapy was given.

The accompanying chart shows the maximum and minimum rectal temperatures. The penicillin dosage and the routes of administration are also summarized.

On June 13, 1945 the patient was discharged from the hospital. While she was hospitalized she had received a total of 10,740,000 units of penicillin intramuscularly and 250,000 units intrapleurally. The hemoglobin level at the time of her discharge was 12 Gm. per hundred cubic centimeters; the erythrocyte count was 3,950,000 and the leukocyte count 14,600, per cubic millimeter, with 71 per cent polymorphonuclear cells. A roentgenogram of the chest on discharge revealed that the heart was of normal size, shape and position and that there was a thickening of the pleura in the right costophrenic angle. The murmur heard to the left of the sternum was soft, faint and not transmitted. At no time during the illness was the spleen palpable or were there peripheral embolic phenomena.

Since discharge the patient has been most cooperative and has reported for reexamination regularly. She has remained free of symptoms and has gained considerable weight. She appears to be a healthy Negro girl at the present time. She is free of symptoms and is regularly employed for light housework. The pulse rate has varied between 80 and 86 per minute. The systolic blood pressure varies between 115 and 125 mm. of mercury, and the diastolic pressure, from 75 to 80 mm. of mercury. A soft, blowing nontransmitted murmur is heard to the left of the sternum in the second intercostal space. Recent studies of the blood reveal a hemoglobin level of 13.0 Gm. per hundred cubic centimeters; the erythrocytes number 4,230,000 and the leukocytes 7,400, per cubic millimeter.

COMMENT

At the time of admission of this patient there were no evidences of endocardial involvement. The period of illness prior to entry had been brief. The clinical picture appeared to be that of a severe gonococcic pelvic inflammation with an associated hepatitis. For many years hepatitis has been observed with severe gonococcic infections. It would seem that during the period of observation the pulmonary valve was involved. The evidence for an acute infective endocarditis in this patient was the appearance of a systolic murmur and a systolic thrill to the left of the sternum in the second interspace. The clinical and roentgenologic evidence of multiple pulmonary infarction confirms this thesis. Indeed, the development of an empyema secondary to pulmonary infarction offered the only means of bacteriologic diagnosis. Blood cultures consistently remained sterile.

It seems reasonable to postulate that this patient had an acute vegetative endocarditis due to the gonococcus which involved the pulmonary valve.

Recovery from acute gonococcic endocarditis is indeed a rarity. Futcher and Scott[2] commented on this in reporting the recovery of 1 of 4 patients treated with a sulfonamide compound. My patient has remained apparently well for over eighteen months after her discharge from the hospital.

---

[2] Futcher, P. H., and Scott, V. C.: Four Cases of Gonococcal Endocarditis Treated with Sulfonamides with Recovery of One, Bull. Johns Hopkins Hosp. 65: 377, 1939.

SUMMARY

A case of probable acute gonococcic endocarditis of the pulmonary valve was treated with penicillin. Bacteriologic evidence rests with the recovery of a gram-negative diplococcus from empyema fluid. The clinical course of the patient has been uneventful for eighteen months after her discharge from the hospital.

AGGRAVATION OF A GASTRIC ULCER FOLLOWING DORSOLUMBAR SYMPATHECTOMY

HALWARD M. BLEGEN, M.D.
and
ARTHUR R. KINTNER, M.D.
Missoula, Mont.

In recent years there has been an increasing interest in the neurogenic factor in the etiology of gastroduodenal ulcer. Abundant clinical and experimental evidence suggests that increased excitability of the parasympathetic nervous system will aggravate the clinical course of the ulcer syndrome. The adverse effects on an ulcer of psychic stimuli, such as worry and anxiety, are well known. Cushing[1] in 1932 demonstrated the frequent occurrence of ulcers and erosions of the gastric mucosa in patients with organic lesions of the midbrain. He also suggested that these lesions were caused by nervous stimuli from the higher brain centers relayed to the stomach through the vagal pathways.

Dragstedt[2] and his associates at the University of Chicago, acting on the concept that the associated gastric hypersecretion and hypermotility are largely neurogenic in origin, have sectioned the vagus nerves in over 90 patients with gastroduodenal ulcer. Although undesirable symptoms were noticed temporarily in a few cases because of gastric retention, in most instances there was prompt and persistent relief of the ulcer distress, prompt healing of the ulcer crater, reduction in the gastric tonus and motility and a definite reduction in the volume and acidity of the gastric secretions. The cases have not been followed for a sufficient period of time to warrant final conclusions, but the results obtained to date have been decidedly impressive.

The effect of the sympathetic nervous system on gastric function and also on the clinical course of peptic ulcer has not been so clearly presented. To a limited extent the sympathetic and parasympathetic systems have a synergistic and antagonistic relationship. In the stomach, however, the effects produced by nervous stimulation are modified considerably by other factors, such as the local automatic tonus of the gastric musculature and the hormonal content of the blood.

It is fairly well proved that sympathetic stimulation will produce decreased tonus and motility of the stomach, spasm of the pylorus and cardia and increased local vasospasm, but the effect of such stimulation on gastric secretions is still uncertain. It is the opinion of Dragstedt[2] that no change would be expected. Kuntz,[3] however, states: "Although interruption of either the vagus or sympathetic nerves supplying the stomach . . . (in most instances) . . . was followed by no marked changes in gastric secretion, the results observed do not warrant the conclusion that gastric secretory activity is not subject to nervous influences. The assumptions, that gastric hyperacidity commonly is associated with parasympathetic hyperirritability, and gastric hypoacidity with sympathetic hyperirritability are supported by ample experimental and clinical data."

Accepting the antagonistic relationship of the two systems, it seems plausible that if vagotomy has a favorable effect in the treatment of ulcer then sympathectomy will have the opposite effect—namely, aggravation of the ulcer. The following case report is of interest because it offers evidence which suggests that this assumption is correct.

REPORT OF A CASE

A man aged 39 was first seen by one of us (A. R. K.) in April 1944. The patient gave a history of severe headaches, vomiting and blurring of vision for two to three months. He also gave a history of mild epigastric distress off and on for one or two years. The epigastric distress was relieved by the ingestion of milk and bicarbonate of soda. His past history was noncontributory except for an appendectomy in 1922, a tonsillectomy in 1919 and the usual childhood diseases.

Examination revealed a well developed, well nourished man aged 39, weighing 135 pounds (61 Kg.). His blood pressure was 250 systolic and 130 distolic. Examination of the eye grounds revealed hemorrhages and exudate 3 plus, edema of the optic disks and vascular sclerosis. Examination of the lungs, heart, thyroid and abdomen revealed that all were essentially normal. There was moderate peripheral vascular sclerosis. Urinalysis revealed specific gravity 1.015, p_H 6, a trace of albumin, 20 to 30 red blood cells and 20 to 30 white blood cells. The blood urea was 72.7 mg. per hundred cubic centimeters, the red blood cell count was 4,460,000, the hemoglobin 13.9 Gm. and the white blood count 10,150, with 87 per cent polymorphonuclear leukocytes. A roentgen examination of the chest and heart revealed essentially normal conditions. Fluoroscopic examination of the stomach revealed a small prepyloric gastric ulcer. Gastric analysis unfortunately was not performed.

The diagnosis of malignant hypertension was made, and the patient was referred to Dr. Paul Flothow,[4] neurosurgeon, for sympathectomy. In April 1944 an extensive Smithwick type of operation was performed, removing the splanchnic nerves from the seventh dorsal to the second lumbar vertebra inclusive. The symptoms of hypertension improved remarkably after operation. The blood pressure dropped to 140 systolic and 90 diastolic, and it has remained there since. The changes in the eye grounds improved, as did the blurring of vision and the headaches. While convalescing from the surgical intervention the patient had a severe gastrointestinal hemorrhage, vomiting fresh blood and passing blood by rectum. The bleeding was controlled by a medical regimen. In spite of the repeated hemorrhages, the patient had practically no pain due to the ulcer, but he did complain of intermittent eructation. One month later, in June, he had a second severe hemorrhage, and again in July, a third. Gastric analysis two months after the sympathectomy revealed a free hydrochloric acid of 64 degrees and a total acid of 75 degrees. Roentgen examination at that time showed a deep ulcer crater on the lesser curvature of the stomach in the prepyloric area and considerable pylorospasm.

Finally, in September, a radical subtotal gastric resection was performed by one of us (H. M. B.), removing four-fifths of the stomach. Gastrointestinal continuity was restored by a posterior, short loop, Hoffmeister anastomosis. Pathologic examination of the stomach revealed a large prepyloric gastric ulcer on the lesser curvature and also an old, healed scarred ulcer in the first portion of the duodenum. There was no evidence of malignant growth.

The convalescence was uneventful. The patient gained weight. He was relieved of his gastric complaints, and for the past year he has been in good health. His blood pressure has ranged between 140 to 160 systolic over 90 to 100 diastolic. Three gastric analyses have been made since the operation, and these all reveal no free hydrochloric acid, even after stimulation with histamine. Roentgen examination shows only a small portion of stomach remaining with a good functioning anastomosis.

It is unfortunate that we do not have in this case adequate studies on the gastric secretions, but when the patient was first seen the symptoms of hypertension so overshadowed the symptoms of ulcer that studies of the gastric secretions were not performed. However, after the sympathectomy there was a decided elevation in free hydrochloric acid.

[4] Flothow, P.: Personal communication to the authors.

A similar case is reported by Weeks, Ryan and Van Hoy[5] in a recent issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

A man aged 47 had a duodenal ulcer plus malignant hypertension. A complete transthoracic vagotomy was performed, and at the same time the left thoracolumbar sympathetic chain was removed from the fifth dorsal to the second lumbar vertebra. Subsequent to this the patient did well. His ulcer symptoms were greatly relieved, although he was troubled somewhat on the fifth and sixth postoperative day with mild gastric dilatation. This was relieved by intragastric suction. The second stage sympathectomy was performed two weeks later, removing the right thoracolumbar sympathetic chain, also from the fifth dorsal to the second lumbar vertebra. After the second operation the patient became extremely ill and finally died on the fifteenth postoperative day. Autopsy revealed a perforated duodenal ulcer with general peritonitis. An interesting feature in this case is the absence of abdominal pain in the presence of a perforated ulcer with peritonitis. The authors state: "The patient's failure to have acute pain ordinarily associated with a perforating ulcer may have been due to the removal of the viscerosensory fibers associated with the sympathetic side of the autonomic nervous system."

COMMENT

These 2 cases offer convincing evidence that extensive resection of the sympathetic nerve supply to the stomach will have a harmful effect on the clinical course of gastroduodenal ulcer. In both cases the sympathetic resection was performed for malignant hypertension, and it is significant that in both cases the resection was extensive, extending from the fifth and seventh dorsal to the second lumbar vertebra. Our patient with a gastric ulcer had three massive hemorrhages shortly after sympathectomy but finally recovered after a subtotal gastric resection. The patient whose case is reported by Weeks, Ryan, and Van Hoy[5] had a duodenal ulcer which perforated, causing death from peritonitis on the fifteenth postoperative day. It is of interest that the sympathectomy relieved the ulcer pain in both these cases, even though the pathologic process continued. This confirms the view that sensations of pain produced by ulcer are transmitted through the sympathetic nerves.

In reviewing these 2 cases we are aware that in 1942 Froehlich, Stephan and Froehlich[6] reported 4 cases of gastric ulcer in which sympathectomy was performed (splanchnic resection with removal of the first two lumbar ganglions). In all of them the distress was relieved and the ulcer crater showed radiographic evidence of healing.

In 1945, however, Sicard, Albot and Tricard[7] reported 8 cases of gastroduodenal ulcer which contradict these observations. Five of these were submitted to bilateral and three to unilateral splanchnicectomy. The first two lumbar ganglions were removed in 2 cases. Although there was some relief of ulcer pain and distress within the first few months, there was no demonstrable change in the appearance of the ulcer crater and there was not a single durable cure. Five were submitted to gastric resection within eighteen months after operation.

In consideration of these observations it is reasonable to assume that the improvement noticed in the 4 cases reported by Froehlich, Stephan, and Froehlich was probably coincidental and not directly related to the sympathetic resection. It is significant that in these cases the resection was incomplete. Hartzell[8] in 1929 demonstrated that vagotomy is ineffective unless all the vagal fibers are divided, and it is probable that the same holds true for the sympathetic nervous system. The relief of pain and distress may be explained by the fact that the nervous fibers conducting the ulcer pain sensations have been sectioned.

THE SUCCESSFUL TREATMENT OF ACUTE RENAL FAILURE BY PERITONEAL IRRIGATION

WILLIAM E. GOODYEAR, M.D.
and
DONALD E. BEARD, M.D.
Atlanta, Ga.

Acute renal failure in which irreversible changes have not occurred in the kidneys is not an uncommon condition, and the mortality in such cases is tragically high because of the accumulation of substances which are normally excreted by the kidneys. A considerable reduction in this mortality may be expected by an artificial means of removing these substances, thereby prolonging life while the kidneys recover sufficiently to resume function. Such an artificial method is applicable to numerous conditions which cause acute renal failure: transfusion reaction, toxicity to sulfonamide compounds, poisoning with heavy metals, toxemia of pregnancy and severe trauma.

The idea of artificial removal of the substances ordinarily excreted by the kidneys is not new. Abel, Rowntree and Turner[1] in 1914 demonstrated a method of dialyzing these substances from the circulating blood of living animals by a system of celloidin tubes interposed in the vascular system. Putnam[2] in 1923 showed the effectiveness of the peritoneum as a dialyzing membrane.

These methods have received new attention in the past several years at the hands of two groups of investigators. Kolf and Berk[3] of Amsterdam, Holland, have developed further the artificial kidney, which consists of a cellophane tube immersed in a solution of 0.6 per cent sodium chloride, 0.2 per cent sodium bicarbonate, 0.04 per cent potassium chloride and 2 per cent dextrose. The circulating blood is passed through this apparatus from a cannula in the radial artery and back into the body by a cannula in a vein of the foot or forearm.

Seligman, Frank and Fine[4] of Boston have utilized the peritoneum as a dialyzing area, using a modification of Tyrode's solution. They performed valuable experimental work and reported successful results of peritoneal irrigation in the case of a patient with uremia due to parenchymatous damage of the kidney by sulfathiazole. They have also reported the treatment of 2 patients for transfusion reaction and of 1 patient for uremia due to urinary obstruction.

The management of the case reported herein was based on the work of Seligman and associates,[4] who applied peritoneal irrigation to a patient with uremia due to transfusion reaction. No originality is claimed by us. This case is reported as an addition to the series already in the literature, in the hope that it may make a small contribution to the development and perfection of a lifesaving procedure. It is believed that the present report is the first for successful management of acute renal failure due to transfusion reaction in a solitary kidney.

TECHNIC

The procedure as described by Frank, Seligman and Fine[5] was followed in general, but certain modifications were necessitated by the facilities at hand.

The modified Tyrode's solution was prepared first, in readiness for irrigation as soon as the tubes were inserted. The constituents of the solution, per liter, are as follows: sodium chloride 8.0 Gm., potassium chloride 0.2 Gm., calcium chloride 0.1 Gm., magnesium chloride 0.1 Gm., sodium biphosphate 0.05 Gm., sodium bicarbonate 1.0 Gm., dextrose 1.5 Gm., sulfa-

diazine sodium 0.1 Gm., heparin 0.5 mg. and penicillin 5,000 units. The solution was made up in 1 liter infusion flasks and was autoclaved, except that the sodium bicarbonate, sulfadiazine sodium, heparin and penicillin were withheld and added to each flask as it was used. It was feared that the latter constituents would not stand autoclaving, especially the sodium bicarbonate, which would decompose with the formation of toxic substances. The sulfadiazine and penicillin were included to combat infection, and heparin was added to prevent fibrin formation and adhesions. The insertion of the peritoneal tubes was a relatively simple procedure performed under local anesthesia, using two 30 F. mushroom catheters. The recommended flank position was impossible on the right because of the lumbar nephrectomy incision, so the right tube was placed through a high McBurney incision near the iliac crest. The left tube was inserted through the flank. The peritoneum was closed snugly around the catheters, the incisions were closed in layers with catgut, and the skin was closed with black silk. Both catheters were anchored to the skin with silk sutures.

The irrigating solution was attached to the right catheter, using a drip method by which the rate could be measured and controlled. A bacterial filter, though desirable, was not available. The arrangement was such that it was necessary only to handle the infusion flask and not to tamper with the connection of the tubing and catheter.

The left catheter was connected to a constant suction apparatus in the wall. Interposed in this system was a sterile 1 gallon (4.4 liter) bottle as a trap to catch the fluid. There was also a small, guarded air vent to prevent too forceful suction against any portion of the intestine.

The proposed irrigation rate of 1,000 to 1,500 cc. per hour could not be achieved. Inflow was easily possible at that rate, but not the outflow, which attained only about 500 cc. per hour. After great distention of the peritoneal cavity, the inflow had to be retarded to correspond to the overflow. The average irrigation was 500 cc. per hour for two days and 300 cc. per hour for the latter two days. The recovered washings were carefully saved for analysis.

Removal of the tubes was accomplished under light anesthesia with pentothal sodium.

REPORT OF A CASE

Mrs. M. E. K., a white woman aged 35, was admitted to the urological service, Grady Memorial Hospital, Atlanta, Ga., on June 12, 1946. Three weeks previously she had consulted her physician for pain in the right side of her abdomen and in her right flank, without urinary symptoms. He found a large mass in the right upper quadrant of her abdomen, and an excretory urogram revealed a large solitary calculus in the upper pole of an exceedingly large right kidney. She was subsequently admitted to this hospital.

Physical examination showed her to be in satisfactory general condition. The presence of a mass occupying the whole right hypochondrium and extending to a level 3 to 4 cm. below the umbilicus was confirmed. Her general appearance was that of chronic illness with some loss of weight.

Urologic examination revealed a poorly functioning right kidney with thick, purulent, offensive urine from it. The left kidney excreted normal urine and had good function. Retrograde pyelography indicated that the left kidney was anatomically normal but that the right was enlarged in all dimensions. There was pronounced intrarenal hydronephrosis, with an irregular calculus measuring 4 by 5 cm. occupying the upper calyx.

Laboratory studies were as follows: Catheterized bladder urine was normal except for innumerable pus cells and a strongly positive test for albumin. The examination of the blood showed mild anemia with a red blood cell count of 3.6 million and hemoglobin of 9.2 Gm. per hundred cubic centimeters. The white blood cell count was 6,000. The nonprotein nitrogen was 38 mg. per hundred cubic centimeters. The blood calcium and phosphorus determinations were normal on three successive days. Her blood type was 4 (O), Rh positive.

On the basis of these examinations, a right nephrectomy was performed on June 15, 1946, using cyclopropane anesthesia. Considerable difficulty was encountered in freeing the organ from surrounding structures, and severe bleeding ensued. In spite of transfusions of whole blood and plasma the patient suffered profound shock during the latter half of the operation. In the course of the procedure she received 1,500 cc. of type 4 (O) blood, Rh positive, and 600 cc. of blood plasma. For several hours after the operation the patient remained in mild shock, but her blood pressure returned to its original level within twenty-four hours, during which period she had been given another 500 cc. transfusion of whole blood, type 4 (O), Rh positive, and 500 cc. of blood plasma.

Decided oliguria was observed during the postoperative period. The output was 175 cc., 135 cc. and 20 cc. for the next three days, and these specimens contained both red cells and hemolyzed blood. A diagnosis of transfusion reaction, hemolytic type, was made. Severe involvement of the single left kidney was indicated by suppression of urine and rapidly increasing azotemia. The nonprotein nitrogen was 69 mg. per hundred cubic centimeters on the second day and 86 mg. on the third day postoperatively. The blood count was maintained at its original level by the transfusions, but the patient became stuporous with uremia. Infusions of isotonic solution of three chlorides and alkalinization with sodium bicarbonate given intravenously failed to promote the excretion of urine. Within three days the patient's condition had become critical.

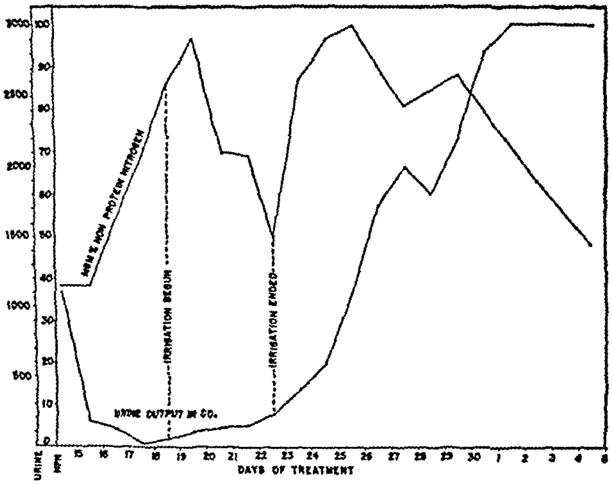

Fig 1.—Relationship of azotemia to urinary output.

Peritoneal irrigation was instituted on June 18, 1946 about eighty-four hours after nephrectomy. The procedure was initiated under local anesthesia and was well tolerated by the patient. Continuous irrigation was maintained for four days. Penicillin was administered parenterally during this period, and a Levine tube was kept in the stomach with constant Wangensteen suction. Each day 3,000 cc. of fluid was given intravenously in the form of isotonic solution of three chlorides and dextrose.

Beneficial results of this therapy were observed almost immediately. The azotemia receded from 86 to 50 mg. of nonprotein nitrogen per hundred cubic centimeters in four days, and the urinary output, which increased in four days from 20 cc. to 240 cc. per day, was now clear and not bloody. The patient made a remarkable clinical improvement also. She became oriented, alert and optimistic.

The peritoneal irrigation was discontinued on June 22, 1946 after four days of continuous use. The level of nonprotein nitrogen immediately rose again to 100 mg. per hundred cubic centimeters within three days, but the urinary output increased each day, up to 2,800 cc. on the twelfth day, by which time the nonprotein nitrogen had receded to 62 mg. per hundred cubic centimeters. By now the patient had made a striking recovery and was eating well and sitting up.

Examination of the recovered peritoneal washings on the second day showed that the urea content was 47 mg. per hundred cubic centimeters, and on the fourth day it was 53 mg. The urine which began to be excreted after resumption of renal function had a urea nitrogen level of 100 to 140 mg. per hundred cubic centimeters, and the specific gravity remained at 1.010 to 1.012. The day to day relationships of the nonprotein nitrogen level, the urinary output and the urea clearance through peritoneal washings are graphically presented in charts 1 and 2.

When the peritoneal tubes were removed, they were seen to be covered with an exudate, but the patient never showed clinical evidence of peritonitis. She had pronounced distention, but peristalsis was always heard. She was taking fluids by mouth throughout the illness, though for ten days there was suction applied to the stomach tube. Her temperature never showed a septic rise, but stayed below 100 F. A blood sulfadiazine level of 5 mg. per hundred cubic centimeters was reached by absorption from the peritoneal irrigation.

In the period of urinary suppression, progressive edema of the legs and trunk was noted and became well defined. There was moderate pulmonary edema with embarrassment of respiration, but this never appeared critical. Also during the height of azotemia there was acidosis, as manifested by a carbon dioxide combining power of 39 volumes per cent. Intravenous fluids were restricted to combat the edema, and sodium bicarbonate and 10 per cent dextrose were given for correction of the acidosis. Both the edema and the acidosis subsided satisfactorily after the resumption of renal function.

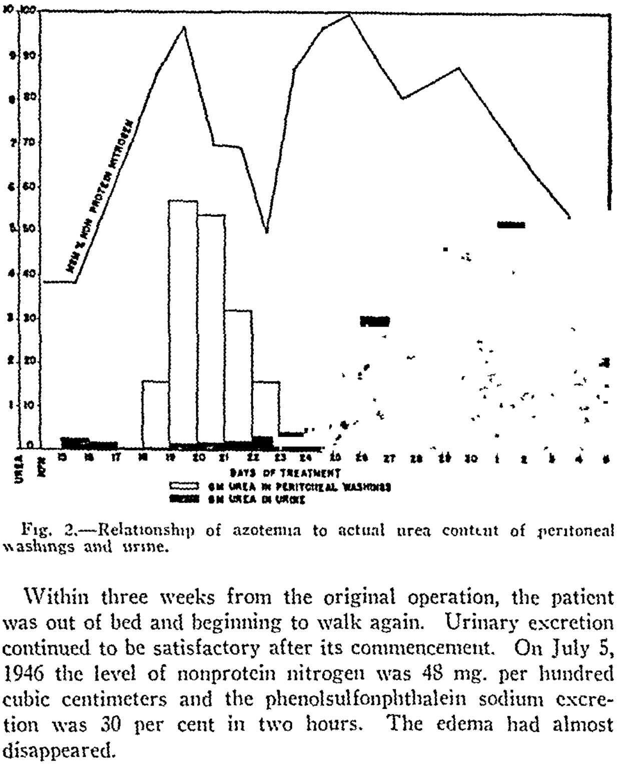

Fig. 2.—Relationship of azotemia to actual urea content of peritoneal washings and urine.

Within three weeks from the original operation, the patient was out of bed and beginning to walk again. Urinary excretion continued to be satisfactory after its commencement. On July 5, 1946 the level of nonprotein nitrogen was 48 mg. per hundred cubic centimeters and the phenolsulfonphthalein sodium excretion was 30 per cent in two hours. The edema had almost disappeared.

On July 12, 1946, one month after admission, the patient was discharged from the hospital. She has been followed for four months since that time and is doing well. She is gaining weight, feeling well and doing her housework. There is some residual impairment of renal function, as manifested by fixation of the specific gravity of her urine at 1.010 to 1.012 and by the phenolsulfonphthalein excretion of 40 per cent in two hours.

COMMENT

Peritoneal irrigation is a formidable procedure and not to be undertaken lightly, mainly on account of the risk of peritonitis. The decision to initiate this procedure was reached in this case because it appeared that the patient was going to die, which justified any lifesaving effort.

We cannot state definitely that the patient would have died or that she was saved by the procedure, but the results were decidedly striking. The azotemia began an immediate recession and the formation of urine was resumed. When the irrigation was suspended the azotemia quickly took an upward turn, which gradually decreased as the output of urine increased. The patient's recovery was the remarkable feature, since she had been expected to die, and this recovery appeared to be directly related to the irrigation.

The actual amount of urea recovered in the washings was small in comparison with that reported to have been recovered by others. The patient was a small woman; she received little protein in the three preoperative days and was receiving no protein during the peritoneal irrigation. The amount of urea removed was enough to reduce the nonprotein nitrogen level, and chart 2 shows that it was as high as the amount in the urine two weeks later, when renal function alone had reduced the nonprotein nitrogen level to 48 mg. per hundred cubic centimeters. This demonstrates that it was a significant amount.

The greatest problem technically in our experience was the outflow of the peritoneal irrigation. It constantly required attention and manipulation and never allowed the desired irrigation rate of 1,000 to 1,500 cc. per hour. Fine, Frank and Seligman[6] used a stainless steel suction tube with numerous perforations, which was placed through the flank and well down into the pelvis. This should be much more effective than the simple mushroom catheter.

The inflow never caused any difficulty. It had to be retarded to correspond to the outflow, so as not to overdistend the peritoneal cavity. A bacterial filter should be used in the inflow apparatus.

For the sake of others who might undertake the procedure for the first time, it should be emphasized that it is complicated and tedious. It requires full time special nursing and a great deal of time and attention on the part of the physician. Adequate laboratory facilities are almost indispensable.

Fluid balance and acid-base balance are probably as important as the reduction of the azotemia. Excess intravenous fluid produces edema, which may be disastrous in the lungs or brain. Acidosis is always present, and requires the administration of dextrose and alkali compounds. Electrolyte studies of the plasma were not made in this case, but they should be done with a view toward variation of the irrigating fluid to maintain the electrolyte balance.

SUMMARY

1. Peritoneal irrigation is confirmed as an effective method of treating uremia.

2. It has been successfully used in a case of acute renal failure due to transfusion reaction in a solitary kidney.

A Welter of Material Aids.—The impact of modern civilization and scientific progress has engulfed the physician in a welter of material aids, a maze of imposing buildings and a host of essential personnel that would bewilder a less intrepid soul. He must whet his education on the grindstone of endless mechanisms while balancing his diagnostic and therapeutic skills with the verdict of the laboratory or the latest gadget he must employ to keep up with the times. Liberated at last from empiricism, he must today chart a course between the auxiliary medical service he does not perform and fragmentation by specialization. In the modern practice of medicine, physicians shrink relatively in numbers within the rapidly expanding structure of his workaday world. Already surrounded, how long before he will be submerged by this intricate framework of innumerable ancillary and elaborately staffed, essential services? Superimpose government control, so imminently threatened, on this and the relation of the physician to the whole structure of medicine declines alarmingly in importance. Weaken the keystone of the arch and the entire structure is imperiled. Reduce the practitioner of medicine from his high estate of servant of the public and devotee of culture to the role of slave to government and the top-heavy superstructure cracks, topples, then comes crashing down on that public with devastating effect.—Abridged from the *Journal of the Florida Medical Association*, March 1947.

Council on Physical Medicine

The following article has been adopted by the Council on Physical Medicine:

The Council wishes to express its appreciation for the valuable cooperation of the Consultants on Ophthalmic Devices in reviewing this article. The consultants are Drs. Walter B. Lancaster, chairman; Thomas D. Allen, S. Judd Beach, Conrad Berens, Frederick C. Cordes, Alfred Cowan, William H. Luedde, Lawrence T. Post, Avery D. Prangen and Kenneth C. Swan. This paper was also submitted to the American Orthoptic Council and embodies the criticisms and suggestions of that council.

HOWARD A. CARTER, *Secretary.*

ORTHOPTICS

(Second Paper)

WALTER B. LANCASTER, M.D.
and
JULIA E. LANCASTER, M.A.
Boston

Orthoptics deals with binocular vision. The orthoptic technician has to deal with the stumbling blocks to binocular vision which must be overcome in order to establish normal binocular vision. What are the obstacles to be overcome? Or, to put the same question in another way, what are the causes of orthoptic failure?

One can list the obstacles to normal binocular vision by determining to which of four main classes the patient belongs: 1. Is it possible for the patient to straighten his eyes or are there insuperable obstacles to binocular vision? 2. Can he learn to know what his eyes are doing? Can he recognize his errors in fusion? 3. Can he be comfortable fusing habitually? 4. Does he desire to use his eyes correctly? These will be amplified and explained, and then the three ways in which these problems can be attacked by the orthoptic technician will be enumerated and developed.

1. Is it possible for the patient to straighten his eyes—has he got it in him to straighten his eyes? If not, then his is not a case for orthoptics. Orthoptics deals only with cases in which there is no insurmountable obstacle.

It is not possible to tell by inspection whether the patient can or cannot straighten his eyes. The mere size of the deviation is surely not enough to warrant the assertion that he cannot, after suitable training, straighten his eyes; but it is often possible to say that if first he has some surgical intervention performed to reduce the deviation (*a*) he will be much better able to straighten them and (*b*) it will take less time to straighten them. This applies to certain types of deviation much more than it does to others.

Note that the reason why this patient will not be able to straighten his eyes is not for the orthoptic technician to give, although often her opinion may be extremely valuable to the ophthalmologist. But, essentially, the problem is up to the ophthalmologist. He may find congenital anatomic defects that preclude normal binocular vision as a habit: (*a*) Some of these are visual defects. A visual acuity below 6/20 does not make binocular vision with fusion and depth perception impossible of attainment on the major amblyoscope, but it makes the use of binocular vision in casual seeing as a habit decidedly improbable. (*b*) Some are orbital defects. (*c*) Some of the defects in the neuromuscular system are above the orbital and muscular level inside the cranium, perhaps nuclear or supranuclear. These are the defects that are difficult to find without prolonged work on the patient. Certain forms of paralysis are temporary and the patient recovers in a few months, leaving deviations which can be helped by orthoptics; but most paralyses belong in the class of insurmountable obstacles to binocular vision as far as orthoptics is concerned. Neither the orthoptist nor the ophthalmologist can always tell by inspection (i. e., by one or two careful and thorough examinations) whether or not there are insurmountable obstacles.

This is illustrated by the case of a young girl who had had five surgical operations and whose muscles were pronounced by the surgeon too attenuated for further surgical intervention until she was perhaps five years older. The technician found an esotropia of 20^{Δ}; after long treatment she was able to teach the patient to fuse and to read binocularly. At the time of reporting, the patient did not habitually fuse for distance yet her deviation was reduced to 10^{Δ} and with prisms base out she was well on the road to binocular vision. The ophthalmologist had definitely pronounced the case incurable.

Thus it is often impossible for surgeon or orthoptic technician to decide at once whether the case is one in which the patient cannot straighten his eyes after suitable treatment. And the inference is justified that as knowledge and skill increase the number of patients in this group will diminish.

2. Can he learn to recognize his errors of fusion? In order to correct them he must be aware of what he is to correct. This is the first step in orthoptic training in many cases. The patient must be taught to recognize diplopia. There are several tools or methods of dealing with it which will be taken up later. The important point now is to understand what is meant by the question: Can he learn to know what his eyes are doing? For example, when the eyes cross, diplopia should result; it does result in normal persons. Can this patient learn to see double? That is the first step in the process of teaching him to fuse and see single binocularly instead of seeing single by suppression, as is his habit.

3. Can he be comfortable fusing habitually? A patient may be trained to fuse on the synoptophore, but if he is to maintain fusion in casual seeing as a habit he must have the reflex of fusion reinforced by the satisfaction of comfort. He has been squinting and suppressing because it was the most comfortable way of seeing. It is not to be expected that he will adopt the new way of binocular single vision unless it is made a comfortable way.

This applies to patients with phorias in particular, since they do fuse, but the patients sent to the orthoptist complain of more or less severe discomfort due to

---

This paper was written in response to a request from the Council on Physical Medicine for a second paper amplifying the original paper, "What is Orthoptics?" which was published Feb 16, 1946, by giving in more detail an account of the actual work performed by an orthoptic technician This is not an attempt to cover the whole field of orthoptics but an attempt to give as accurate and definite an outline as possible of some of the most important things an orthoptic technician has to do in her daily work, about which most medical practitioners have imperfect and inaccurate information. It is not to be expected that all will agree as to what functions to emphasize. We have presented those which we consider the most important.

the effort of maintaining fusion. Unless this can be overcome the case will have to be listed as a failure for orthoptics.

4. Does the patient desire to use his eyes correctly? This is a matter of motivation. Since taking a course of orthoptics, which often involves tedious work at home as well as frequent visits to the orthoptist, may be more of a task than the patient and his parents are willing to go through with, it is one of the stumbling blocks to success.

When the orthoptist receives a new patient the first important step is to classify the case to determine what problems are to be treated—in short, to make a diagnosis. But note that the important part of the diagnosis from an orthoptic point of view is what may be called the functional diagnosis rather than the anatomic diagnosis, which often is the chief interest of the ophthalmologist.

There are four ways of using the two eyes together: (1) normal binocular vision; (2) binocular vision with diplopia; (3) suppression, and (4) anomalous correspondence.

The first step is to ascertain the group in which to place a particular patient, since the treatment differs for the different groups. For example: A patient comes in with convergent strabismus. It is apparent that he is fixing habitually with his right eye and suppressing his left. The first orthoptic step is to deal with the suppression.

Of course, the ophthalmologist has not only previously examined the patient but prescribed glasses if needed and carried on treatment for amblyopia by occlusion until the vision has improved to the point where binocular vision is possible. Some ophthalmologists prefer to have the orthoptic technician take charge of the occlusion treatment, since it often requires attention to various details besides the occlusion, such as stimulating the use of the eye which is the laggard by various devices, such as pictures, movies and the like. Occlusion is of the greatest importance in two ways. First, by covering the good eye it compels the use of the amblyopic eye, thus causing the sight to develop in the poor eye, which otherwise would become permanently nearly blind—amblyopic. Occlusion is effective before 6 or 7 years of age during the years when the eyesight is developing. If treatment is postponed or neglected during this critical period, it becomes too late and treatment is usually of no avail. Esotropia can be corrected by operation at any time—even after 70 years of age, but if amblyopia is neglected sight may be gone forever.

In the second place occlusion is often necessary to prevent faulty use of the two eyes together, particularly in anomalous correspondence. While the patient is undergoing treatment by the orthoptic technician, who is aiding in the development of correct habits of binocular vision, it is important not to permit habitual faulty use of the eyes at home. Hence, occlusion of one eye is essential as a means of preventing the bad habits from becoming more and more deeply ingrained. To be most effective occlusion must be continuous, not merely for a few hours a day. After the vision has been brought up to about normal for the age and existing ocular conditions, it can be maintained by practicing occlusion a few hours a day.

There are several ways of carrying out occlusion. 1. The eye can be covered by a patch fastened with strips of adhesive or of Scotch tape. 2. The spectacle lens of that eye can be (*a*) opaque or (*b*) made blurry by rubbing soap on the surface or by stippling with varnish (fingernail varnish, for example) or by having the surface etched with acid. In these cases it is often desirable to prevent looking around the lenses by using leather or plastic fitted to shut off the peripheral vision, as some goggles do. 3. Atropine can be instilled in the eye, thus making distant vision somewhat blurry and near vision very blurry. The family physician should appreciate the importance of occlusion and use his influence to aid in enforcing it.

The same problem of suppression is found in a patient with exophoria, who often suppresses one eye as a way of escape from the great effort he must make to obtain binocular vision. Elimination of suppression is the first step toward relief. Similarly with an alternating strabismus. In fact there is nothing in the field of orthoptics so common and so important as suppression.

4. Anomalous correspondence is one of the common causes of trouble, and the orthoptic technician has to discover and attack this problem.

When one eye is fixating an object and the other eye is not doing so but is deviating, it sees the fixated object out of the corner of that eye and suppresses the image of whatever object is imaged on its fovea. If this occurs and is kept up during the years when binocular vision would normally be developed (before 6 years of age) it not only prevents normal binocular sensory relations from developing but it gives rise to an abnormal (anomalous) sensory relationship between the two eyes. Certain points of the two eyes which normally correspond (i. e., have the same directional value or see things in the same direction) no longer function that way; and when the new abnormal relationship is firmly established it is called anomalous correspondence. At times this is easy to correct, but more frequently its correction is difficult and sometimes even impossible. Thus it is one of the important stumbling blocks to orthoptic success.

What are the tools or measures available to the technician in dealing with the problem which she has found? The problems may be grouped under (*a*) suppression problems, (*b*) vergence problems and (*c*) problems of anomalous correspondence.

SUPPRESSION

The problem in suppression is to teach the patient to perceive—to become aware of—the image on the retina of the suppressing eye. The image is formed on the retina and the stimulus of the image gives rise to the sensation, but the sensation is suppressed and kept from reaching consciousness. With the major amblyoscope it is possible to present images and by suitable rotation of the arms of the amblyoscope to move the images on to the foveas of the two eyes. The patient may be able to see either one when the other is excluded, but when both are presented he probably will suppress one. The orthoptist must teach him to take notice of both. This may take many lessons or it may succeed almost immediately.

Suppression is a normal every day function of the central nervous system. In dealing with his problem of difficult binocular coordination the patient who solves the problem by suppressing the image seen by one eye is making use of a normal function, one which is extremely important in human behavior. Normal persons use it in dealing with physiologic diplopia which otherwise would be decidedly annoying. A most valuable tool in combating suppression is the arousing of awareness of physiologic diplopia, since this is only possible when two eyes are being consciously used. It thus becomes the first step back from abnormal suppression to *teach the child to recognize and become aware of physiologic diplopia.* It has the further great advantage that it can be practiced at home, and progress can thus be greatly accelerated. A striking object such as a white figure on the end of a stick is given the patient to look at. A red filter (glass, gelatin or plastic) before one eye makes the object red to that eye, while to the bare eye it is white. This makes it easier for him to recognize two objects, since the image is perceived by one eye as red, while the image of the same object is perceived by the other eye as white. There are many details to be observed in carrying out this exercise and in adapting it for use at home. A spot on the wall may be used if it is sufficiently conspicuous.

A second device or tool for combating suppression is bar reading, which has been developed into an effective form of exercise. The patient holds a black bar (a band of black pasteboard 20 mm. wide is suitable) a few inches in front of his nose, and he looks at (fixates) a picture on the wall. He should see two black bars, one on each side of the picture. This may take a little, or a good deal, of teaching before he succeeds. The same arrangement is used in looking at a book with pictures, perhaps of animals, which he can frame with the bar seen as two bars, if he can be made to recognize physiologic diplopia. To do this he must use both eyes. Thus he is learning the first step toward fusion—to stop suppressing and to use both eyes. He must first learn to see double and then learn to overcome the diplopia, not, as is his custom, by abnormal suppression but by fusion. Orthoptic binocular exercise cannot be begun until the patient has learned to fixate with each eye. One of the first exercises is teaching the child to hold fixation to the count of fifty with either eye at command. Children too young for this are too immature for orthoptics.

THE VERGENCES

Usually the most striking thing about a patient who has failed to develop normal binocular vision is the deviation of the eye which is not being used for fixation. It is a conspicuous blemish—a form of cross eyes. When an eye deviates the mechanism which should pull it into the correct position is the vergence reflex. If the eyes are diverging the action needed is more convergence. If they are converging *too much, the action needed is* more divergence. And if there is a vertical deviation, sursumvergence is needed. The angle between the visual axes is changed producing more convergence or less convergence, i. e., changing the vergence; hence they are called vergences.[1] Since it is the vergence power that corrects deviation it is obvious that orthoptists are much interested in vergences. Vergence problems, in fact, are second only to suppression problems in orthoptics. In dealing with vergence problems two measurements are vital. The first is the deviation, which should be measured, of course, by the ophthalmologist before he sends the patient to the technician. He has several ways of measuring it. The orthoptic technician also measures the deviation (which she calls "the angle"), generally using the major amblyoscope in a form of the cover test. She flashes the light first on one target, then on the other, and observes the movements of redress which the eyes make as each takes on fixation. Meanwhile the technician keeps changing the angle of the arms until no movement of redress is observable.

The second set of measurements includes the amplitudes of fusion. Starting with the arms of the amblyoscope set at "the angle" the patient is given targets which he can fuse (if he is capable of fusion) and one sees how far he can maintain fusion as the arms are slowly made to converge (or diverge) before the images separate and he sees double. Then the arms are moved slowly back until the images are fused again. The first reading is the "break" point, the second is the "recovery" point. Both are significant. The ophthalmologist uses the rotary prism (or prism bar) to measure the amplitudes of prism convergence and prism divergence in such cases. They are recorded as a fraction, the numerator showing the break point and the denominator, the recovery point.

The most important known cause of convergent squint is hypermetropia. It acts through the accommodation. In order to see clearly, the hypermetropic person has to correct his hypermetropia by accommodating (or by glasses); but accommodation is easier if convergence is done at the same time (accommodation convergence reflex, near reflex). Accommodation and convergence and contraction of the pupil constitute the near reflex. Accommodation and convergence are intimately but not inextricably linked together. Increase of accommodation carries with it increase of convergence. Reduce the accommodation and the convergence is reduced. The ophthalmologist takes advantage of this and prescribes convex lenses to reduce the necessity for accommodation and so to reduce the convergence. In a purely accommodative convergent strabismus this will correct the deviation. In any case it will reduce the convergence to the extent that the accommodation is the causative factor.

There are two problems for the technician in dealing with accommodative squints. The first is the correction of the residual convergence, which is not fully corrected by the convex lenses. The second is the interesting task of teaching the patient to keep his eyes straight without glasses. The first step in this latter task is to teach him to maintain fusion at the expense of accommodation, which means at the expense of seeing blurry. It is the accommodation which makes the images clear on the retina. If the accommodation is relaxed then objects become blurry. If the patient says he is seeing blurry, which means relaxing, then his pupils should dilate somewhat, since they are part of the near reflex. This is a valuable check on the reliability of the patient's statements. One may learn this relaxation readily, another may not. It is easier if the hypermetropia is not too large, which means that the blur is not so great when the hypermetropia is not corrected by the accommodation. The next and final step is to teach the patient to accommodate without converging. He must learn to dissociate accommodation and convergence. One way is to exercise the eyes on the amblyoscope—the other way is to work on objects in the room. One can start with objects at a distance of 6 meters which require the minimum of accommodation in the room. Then move the object 1 meter nearer. This involves but little more accommodation. Then 2 meters nearer, and so on. The eyes may gain rapidly until the object can be moved to 1 meter from the eyes without losing fusion by excessive convergence induced by the impulse to accommodate in the interest of clear vision, and then when it is moved near enough for reading they may snap into accommodation and so converge and lose fusion. This has to be practiced a long time in some cases, but final success is the rule. A similar innervational task is possible on the amblyoscope by inserting minus lenses, gradually increasing them. They call for accommodation and the arms of the amblyoscope may call for no convergence. Thus the patient gets practice in dissociating accommodation and convergence until he can maintain straight eyes and clear vision at the same time—a perfect cure.

---

[1] When one eye alone is being considered its movements are adduction, abduction and so forth and are called ductions. Thus the right eye may be able to abduct 40 degrees and the left the same amount, so that the sum of abductions of the two eyes would be 80 degrees of divergence. As a matter of fact the two eyes can diverge in a normal person only 3 to 4 degrees, showing the fundamental difference between abduction and divergence. Unfortunately, the optometrists have adopted the term ductions as including convergence and divergence and vertical divergence movements. Many ophthalmologists have followed their lead and use the term ductions instead of the correct term vergences. Ductions is correct for optometrists—has the sanction of their leaders. Possibly it will be adopted by the next generation of ophthalmologists, many of whom are lax in their use of terms.

The form of vergence training most widely known is that which aims to increase the amplitude of convergence. The patient is directed to fix a pencil at arm's length and move it in the midline toward the nose until it is seen double because the eyes can no longer converge enough to keep the images on the foveas. The pencil is then moved to arm's length, and the process is repeated. This is done over and over for three to five minutes, several times a day. This is exercising the convergence with the aid of the accommodation, and it is called accommodation convergence. The pencil to nose technic has been amplified as follows (especially in convergence insufficiencies):

1. Move a pencil from arm's length toward the nose until diplopia results.

2. Jump technic: (*a*) Move it a little way toward the nose, close and open the eyes, move a step nearer and close and open the eyes. (*b*) Start at arm's length fusing; close the eyes, move nearer, open and fuse, close the eyes again moving the pencil still more, open and fuse; repeat until fusion fails. By the (*a*) method the patient is fusing while the object is being moved nearer; then the eyes are closed and opened, the patient trying to maintain fusion. By the (*b*) method the eyes are closed while the object is being moved nearer, then opened and fusion held if possible. Method (*b*) is a little more difficult than (*a*).

3. Move the pencil toward the nose until diplopia is reached, then remove the pencil but maintain diplopia of distant objects, i. e., maintain convergence. Care must be taken that the diplopia is homonymous. This can be checked by covering one eye to be sure that the image on the same side as the covered eye is the one that disappears—is homonymous. Or a red filter may be held over one eye to check to see which eye sees the red image; it should be the homonymous eye.

4. Produce voluntary homonymous diplopia at will, on command.

5. Hold the eyes crossed several minutes continuously, perhaps listening to the radio to help pass the time, which seems very long to be holding convergence.

6. Look at a distant object and produce voluntary crossing of the eyes with homonymous diplopia.

One reason the pencil to nose technic is not more effective and does not always produce satisfactory results is because the patient (and the physician, too) does not realize the supreme importance in this exercise of definitely recognizing the diplopia which always occurs when the pencil gets too near for fusion provided that the patient is using both eyes. It is curious how often a patient may go on moving the pencil forward and backward day after day with no improvement. The reason is that he does not attend to and recognize the diplopia. Since he does not notice it he must be suppressing. Since he suppresses he does not use both eyes, therefore he does not improve. Another reason it lacks effectiveness is that what the patient needs is ability to converge without the aid of accommodation, as under heading 6 in the preceding technic. For instance, if the patient has an exophoria for distance, this is overcome by convergence; but if the gaze is fixed on distant objects accommodation is not called for, so he must converge without accommodating. Better results are obtained by exercising the convergence without the accommodation either on the amblyscope by converging the arms or at home by the use of exercise prisms. For example, if the patient has an amplitude of 12/4 diopters of prism convergence, he is given a pair of prisms mounted for convenience in holding them on a spectacle frame without temples.

He may begin with prism 4^{Δ} base out for both eyes, making a total of 8^{Δ}. When this is held before the eyes close to the glasses he is wearing it will make an object across the room appear double, but the fusion stimulus will tend to correct this and make the object appear single by converging the eyes 8^{Δ}. If he cannot fuse an object across the room he must move nearer to it; at a distance of 1 meter he probably will be able to fuse it, aided by winking a few times. Then holding the fusion he walks slowly backward and probably can hold fusion until he moves as far as the room permits. Then the prisms are raised and the object for a fraction of a second is seen double, quickly coming together as he makes the necessary divergence needed to fuse it. Then the prisms are held in front of the eyes again and the process is repeated for three to five minutes, ten times a day or as near ten times as the orthoptist believes the patient is likely to do it with some urging. When the 4^{Δ} prisms are readily overcome the power is increased to 6^{Δ}, then 8^{Δ}, then 10^{Δ}.

This is an exceedingly effective way to improve the convergence amplitude. A similar technic with prisms base in is used for developing divergence amplitudes.

The diplopia technic is also adapted for divergence. The patient fixates a distant object and holds a pencil before the nose. The pencil should be seen double; the diplopia is crossed because the eyes are diverging relative to the distances of the pencil and wall. Then he practices seeing the pencil double at longer distances. A picture may be pasted on the window and seen double when looking at a distant object through the window. Care must be taken that the diplopia is always crossed, which means that the eyes are diverging. When he can back away from the window across the room and keep crossed diplopia, then he should practice the jump technic, closing and opening the eyes and still maintaining the divergence with crossed diplopia and finally diverging at will on command. These two forms of exercise, the prisms held before the eyes while fixating far and near and the learning of voluntary diplopia, homonymous or crossed according to whether convergence or divergence is wanted, are the effective tools for increasing vergences.

ANOMALOUS CORRESPONDENCE

For the treatment of anomalous correspondence one must have a clear idea of the conditions that exist in a patient with this entity. In the first place he is suppressing the images formed on the fovea of the deviating eye. This suppression must be overcome. He must have perception of the image on this fovea aroused and brought to consciousness.

Second, he has anomalous perceptions of images formed on some extra foveal parts of the retina. These must be suppressed. As a matter of fact they usually are suppressed. It is difficult or impossible to arouse physiologic diplopia in many patients, although this would be possible if they were using an extra foveal retinal area as a so-called "false macula." Sometimes monocular diplopia can be elicited. This occurs when the image on the extra foveal area is not only perceived but it is doubly perceived; i. e., it is seen—perceived—in its proper direction and also seen—perceived—in an anomalous direction. In this case the task is to stimulate and establish the normal perception and erase the anomalous one. In arousing the dormant normal foveal response the fovea must be stimulated in unusual ways in order to be effective. Monocular flashing and massage of the macular area are used, but by far the most effective procedure is locking the arms of the amblyoscope at the true angle so that the images are both on the foveas of the respective eyes and then oscillating the arms vigorously through an angle of 30 to 45 degrees as rapidly as possible, several times a second. Note: The mistake is often made of oscillating through too small an angle.

Many patients will respond in a short time to this. In fact if the patient does not respond in the very first lesson the prognosis is not good—not much can be expected even in fifty or one hundred lessons. This is apt to be the case in an older patient (over the age of 12), for whom it is often the wisest plan (in the present stage of the knowledge of orthoptic technic) to advise surgical cosmetic cure and to abandon binocular vision. The use of occlusion is important in certain cases. When that can be dispensed with, however, treatment can be used which cultivates true diplopia, using great care that the patient is not cultivating the false diplopia which is a fundamental tendency in anomalous correspondence.

SUMMARY

To summarize the task of the orthoptist:

1. Be sure that the patient has sufficiently good vision in each eye. Too great a difference in vision between the two eyes is an insurmountable obstacle to the habitual use of the eyes in normal binocular vision.

2. The patient must learn to fix with either eye at command and hold fixation for the count of fifty. Until he can do this he has not reached the age of readiness. Orthoptic efforts are wasted on a patient who is not yet far enough developed to be able to fix with each eye.

3. In most patients the first step toward binocular vision is learning to overcome suppression. Suppression is the patient's way of escape from the difficulties of binocular vision. To retrace the steps he has taken in the wrong direction away from binocular vision, he must learn to see double—learn physiologic diplopia. This may be easy in some cases but long and arduous in others. The skill of the orthoptist has full play here.

4. The patient must begin to use his two eyes together. One of the devices of great value in learning to use both eyes is bar reading. A simple form of framing pictures with a bar held in the hand can be used before the patient has learned to read. His progress will be much more rapid if he is old enough to have learned to read.

The time element, the age of readiness, is of enormous importance Often a child has been subjected to orthoptic treatment for many months before a certain goal has been reached, and a sober appraisal of the results will show that all the progress has been made in the last few weeks after the patient had attained the degree of development which made him ready for the task. All the time devoted to working at the task before the age of readiness could well be saved by not attempting the impossible. Of course, the difficulty is in knowing when this age has been reached. This is one of the things which future progress in the art will make clearer.

5. Meantime, the patient may have anomalous correspondence. If so, this must be corrected. The danger is great of confirming the bad habit instead of curing it by urging the patient to try binocular vision without carefully controlling the methods he uses. Often occlusion has to be used. In some cases it is not worth while to try to overcome anomalous correspondence.

6. When the patient has learned to use his two eyes separately without suppression it is time to see if he can fuse the two images. There is no way to compel fusion. One can present conditions on the major amblyoscope calling for fusion, two images of the object fairly near together and well adapted for fusing into a single image, then if he can fuse he will. The innate impulse to escape diplopia by fusion is what one has to rely on. If he does not do it the first time he may do it the one hundredth time—one has to persist.

7. Amplitudes of fusion must be developed by vergence exercises, of which there is a variety. The philosophic or theoretic basis of orthoptics consists in setting up a situation and putting the patient in a place where he must respond; making the response satisfying (reinforcing the reflex, writers on conditioned reflexes call it); making unsatisfactory responses unsatisfying to the patient, and repeating the satisfactory response often enough so that it is well established.

With the major amblyoscope, the orthoptic technician has the situation firmly under control. There are no extraneous stimuli entering the situation. The technician can control the lights and movement of the instrument and can control the stimulus by the choice of targets so that the patient is almost forced to make a correct response. Once he makes that response he is praised for it and encouraged to repeat it. Thus the patient learns. This is orthoptics.

TROPICAL DETERIORATION

Many people who live in moderate climates believe that tropical climate has a baneful influence on white persons. Men of letters (Kipling, Conrad, Maugham) as well as some students of tropical medicine have expressed similar beliefs. Rogers and Megaw list among contributing causes of "tropical neurasthenia" hot climate, especially when monotonously wet and continuous, and depressing environment with absence of congenial society, poor food and deficient or excessive exercise. Reed [1] described one form of tropical neurasthenia in which patients complain of asthenia, anorexia, easy tiring, palpitation, languor, variable abdominal pains, often unexplained nausea, vomiting and diarrhea. The systolic blood pressure is below normal. The early experiences of our armies in the jungles of Malaya, Burma and the Southwest Pacific strengthened the belief in a specific deleterious, harmful effect of tropical climate on white men. With the development, however, of effective methods for control of malaria, dysentery, heat disturbances and other tropical dangers by the use of new drugs, new methods of controlling insects and infectious diseases, scientifically tested tropical clothing and adequate amounts of water, salt and food, most of the hazards of fighting in the tropics were successfully combated.

Surveys on the health of troops in the tropics made in 1945 by two separate teams [2] throw an interesting light on the importance of nutrition in combating tropical deterioration. The Canadian unit operated in India and Burma, where it studied Indian soldiers exclusively. The United States unit operated in the Central, South, Southwest and Western Pacific, where it studied United States troops, both white and colored. Both teams collected systematic information on feeding policies and practices, on the diet of individual soldiers and groups of soldiers, on health as determined by medical histories and physical examinations, and on physical fitness. Samples of the urine and blood of each person were analyzed in specially constructed field laboratories. The results of these surveys were interpreted by comparing them with data collected in two large scale ration trials conducted under rigidly controlled field conditions during 1944 in North America. The observations in the ration trials were made by the same methods used in these surveys, and 2 members of each survey team had participated in both North American trials. The average nutrient intake was of the same order of magnitude as that for garrison troops in the Pacific and United States troops in training camps in the United States. Scores in tests of physical fitness were at a high level in troops who had recently survived in combat and were less good in rear areas. Distribution curves for the data on hemoglobin, plasma protein, urinary chloride, urinary ascorbic acid, urinary thiamine and urinary riboflavin were similar for United States troops in the Pacific and United States and Canadian infantry in North America. On the basis of clinical findings and biochemistry, cases of classic nutritional deficiency syndromes were not seen. Skin diseases, especially heat rash and epidermophytosis, were common, more so in forward than in rear areas. Moderate weight loss averaging up to 10 pounds was found in troops recently in combat but not in garrison troops. Among United States troops under stress of combat compared with those not exposed to stress, complaints referable to the skin, gastrointestinal tract and neuromuscular systems were more frequent, as were positive physical findings. Their weight was lower, but biochemical status was about the same and physical fitness was actually higher in the groups under stress.

In the present surveys many areas were visited in which good health had been maintained among adult populations when diet was ample and tropical diseases were well controlled. White troops were efficient after continuous presence for as much as two years in severe tropical environments. Under certain well recognized types of stress not peculiar to the tropics, men react and deteriorate similarly in tropical, temperate and cold environments. The surveys stress the importance of variety of food items, foods similar to those the soldier usually eats in ordinary life, the avoidance of caloric deficits and high acceptability insured by good preparation. The proponents of a large intake of vitamins or a low intake of animal protein are not supported by any of these data.

TRANSMISSION OF POLIOMYELITIS TO RODENTS

Direct transmission of poliomyelitis virus from man to mice by the adjuvant use of autolyzed mouse brain tissue was reported recently by Milzer and Byrd[1] of the Michael Reese Research Foundation in Chicago. Most attempts to infect routine laboratory animals with monkey passage strains of poliomyelitis or with infected human tissues failed until 1939. Then Armstrong[2] was able to adapt the Lansing strain from monkeys to cotton rats and from the latter to white mice. Successful adaptation of a few other monkey passage strains by the same technic have been reported,[3] though most attempts to establish monkey passage strains in rodents have been unsuccessful.[4]

In harvesting brains and cords from mice paralyzed following intracerebral injection with the Lansing virus, Milzer observed that autolyzed brain tissue removed from mice left in their cages seven to eight hours after death appeared to accelerate the incubation period in passage mice. The autolyzed brain tissues were bacteriologically sterile. Preliminary experiments showed that the same acceleration could be produced by adding sterile, autolyzed brain tissues from normal mice to stock virus suspensions. Control mice and cotton rats inoculated with the autolysate alone remained normal.

Tests were made as to whether or not autolyzed brain tissues would make possible a direct transfer of monkey passage virus to the white mouse without intermediary passage through the cotton rat. Bacteria free autolyzed brain tissues were obtained from normal mice killed by trauma and kept at room temperature for sixteen hours. Ether was not used for killing, since it seemed to interfere with autolysis. A 10 per cent suspension by weight was made in nutrient broth, which was afterward freed from large particles by filtration through sterile gauze. The reaction was finally adjusted to p_H 4.00 by the use of the Hammon[5] buffer solution.

Ten per cent infected cord suspension from the twelfth monkey passage Leon strain was mixed with an equal volume of brain autolysate and injected intracerebrally into 8 mice. One mouse developed typical paralysis of both front and hind legs by the fifteenth day. This animal was killed. Its brain and cord suspension was mixed with autolyzed brain solution and used to inoculate a second group of 8 mice. These mice developed typical paralysis in from eight to thirty-two days. A fourth passage was similarly made, and all the mice developed typical paralysis in from four to seventeen days. By the fifth passage the incubation period was reduced to from two to nine days. Lesions typical of poliomyelitis were demonstrated on microscopic examination. By the sixth passage the virus was completely neutralized by human immune serum globulin, while control mice developed typical paralysis. Cross immunity tests showed that Lansing immune mice were immune to the Leon strain. Leon immune mice, however, did not show immunity to the Lansing strain.

The autolyzed brain technic was then used for direct transmission from human cases to white mice. Several strains of poliomyelitis virus from infected human feces and spinal cords have thus far been successfully transferred to Swiss mice. Immunochemical typing of these strains is now in progress. The development of a successful polyvalent vaccine is the apparent ultimate aim of the research.

THE THIRD NATIONAL CONFERENCE ON HEALTH IN COLLEGES

On May 7 to 10 representatives from the colleges and universities of the United States will meet in New York City to confer on means of improving the health teaching, the health service and the physical education in our colleges. This Conference on Health in College, coming after the disorganization attending the war and in the midst of the emergency created by the unprecedented postwar college enrolment, promises to be of interest and importance.

From the point of view of medicine much is at stake in this conference. Here is an opportunity to emphasize the place of the college in giving students a knowledge of health and enthusiasm for physical fitness and preventive medicine. If the discussions center about providing students with clinical treatment and hospital care the conference will have failed in its true objective. A college health program can consist merely of an infirmary to which students go when they are too ill to attend classes or it can serve properly in an institution of higher learning to magnify the educational and preventive aspects of a health program. The armed services took many physicians, health teachers and physical educators from our colleges. Some institutions faltered in their health educational and preventive medical efforts during the war years under the necessity of meeting the urgent problems of the sick student. Now the colleges may again be able to take the long range view of their health responsibilities and opportunities and provide health programs designed to turn out graduates who will be leaders in the battle for well organized public health services, efficient sanitation and modern medical care and hospitalization.

In those colleges which consider themselves in loco parentis and therefore obligated to provide medical care, the student health service can be organized on the basis of voluntary prepaid medical care and hospitalization insurance and be an educational experience of real value to the student. Some state institutions, with a medical school faculty available and taxpayers footing the bills, find it easy to ignore the educational implications and provide complete medical care without any effort to relate the costs of the service to the student health service fee. This is spoon feeding medical care to the few chosen for a college career. Many develop the erroneous notion that such services are naturally owed them at little or no cost. In the coming conference the educational implications of the medical services provided our college students should also be given careful study and analysis.

Current Comment

DISSOLUTION OF SUBSTANCE OF TEETH BY LEMON JUICE

Stafne and Lovestedt[1] report observations on 50 patients who were using lemon juice routinely and who showed evidence of dissolution of dental structure. Thirty-nine of these were women and 11 were men, a ratio of approximately 4:1. The patients came from twenty-two states, two Canadian provinces, Mexico and Puerto Rico; apparently such use of lemon juice is widespread. Striking uniformity was recorded as to the manner in which lemon juice was taken, namely by interval feedings in water. Use of lemon juice in self treatment was most common among persons who were suffering from rheumatism. The juice was also used for constipation, to prevent and relieve colds and occasionally as a tonic. When used as a reduction diet, the juice most often replaced entire meals. Most patients were aware of the high vitamin C content of lemons and desired an adequate intake of that vitamin. Defects in enamel produced by action of acid solutions are recognized by rounded margins in contrast to defects produced entirely by mechanical wear, which have sharper margins. The projection of fillings above the surface of the teeth is probably of greatest diagnostic value. These observations emphasize that extensive dissolution of dental structure may occur as a result of drinking lemon juice, particularly if the juice is taken daily and at times other than with meals. An adequate amount of vitamin C can be had without resorting to improper use of lemon juice. In view of its harmful effects on the teeth, the Rochester physicians say that use of lemon juice as a daily drink in any appreciable concentration should be discouraged.

CHANGES IN ARMY TRAINING PROGRAM FOR MEDICAL OFFICERS

The chief of the personnel division in the Surgeon General's Office, Col. George E. Armstrong, recently discussed[1] the army graduate training program. The professional prospects for new medical officers appear improved since Congress authorized a total increase in commissioned officers from 25,000 to 50,000. Of this number the medical department requirement was said to be 5,750, of whom 2,750 would be commissioned in the Medical Corps. The increase would radically change the ratio of Medical Corps officers to the so-called administrative group. The ratio in 1941 was about 17 medical to 1 administrative officer, while under the proposed breakdown of the Medical Department ceiling the ratio will be 1.67 medical to 1 administrative officer. Obviously the chances that a young medical officer would practice medicine in the Army will be much greater. The War Department proposes, Colonel Armstrong said, to eliminate the former haphazard method of training, assigning and retraining the army officer. The new officer will attend basic branch schools and be assigned where the type of professional career for which he is best suited can be ascertained. The War Department has stated that the basic interest of the Army and of the officer will be served by keeping officers who are trained scientists or technical experts in one line of endeavor for the greater part of their entire service. This program should go a long way toward making the Army more attractive for the young physician.

DUSTING POWDERS FOR RUBBER GLOVES

In reporting the results of an investigation on the pathologic changes produced by the deposition of lycopodium spores in human tissues, Antopol[1] in 1933 recorded an incidental case of peritoneal foreign body granulomas due to talcum that had been introduced presumably as a dusting powder on rubber gloves. His observations have since been confirmed and extended by other investigators to include peritoneal adhesions followed by intestinal obstruction and by foreign body granulomas in the rectum, vagina, cervix, brain and healing wounds; the implantation of talcum powder may be regarded as a surgical menace. Seelig, Verda and Kidd[2] have advocated the substitution of potassium bitartrate as being both harmless and efficacious. However, in powdering rubber gloves with potassium bitartrate, unless proper methods are used, especially in sterilization, the results are certain to cause deterioration of rubber gloves. When the standard technic of sterilization is followed and both the powder and the powdered gloves are subjected to 15 pounds of steam pressure for fifteen minutes, the results are uniformly favorable. If too much heat is applied or if the gloves and powder are exposed too long to the proper degree of heat, the gloves are ruined and the dusting effect of the powder is destroyed.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

April 17, 1947.

President Truman Designates May 1 Child Health Day

President Truman proclaimed May 1 Child Health Day. Contrary to usual custom emphasis is being placed on guarding children against accidents. Miss Katherine F. Lenroot, head of the United States Children's Bureau, explained that accidents take an annual toll of almost 20,000 boys and girls under 20. The majority of such deaths are said to be preventable. During the week beginning April 27, efforts will be made to get facts on home accidents before parents. The Social Security Administration and the Federal Security Agency are assisting in this work in cooperation with the National Conference on Home Safety.

Permanent Nurse Corps Legislation

Legislation creating a permanent Nurse Corps in the Army and Navy and a women's medical specialist corps in the Army passed the Senate and was sent to the White House for signing by President Truman. At the present time, Army and Navy nurses hold temporary commissioned rank. Without new legislation at the end of the war emergency they would revert to prewar pay of $1,080 to $1,800 a year, and the services would have been unable to retain their nurses on this pay scale. The new legislation will commission nurses on a permanent basis, as it does male officers, and grant corresponding allowances and benefits. The women's medical specialist corps includes physical therapists, dietitians and occupational therapists.

Washington newspapers followed up the controversy created when Dr. Claude W. Munger, director of St. Luke's Hospital, New York, a past president of the American Hospital Association, accused nurses of having a "to-hell-with-patients" attitude. He reiterated charges made at a hospital conference in Roanoke, Va., and said there had been a changed attitude on the part of nurses toward patients after the American Nurses Association adopted an economic security program last September. Miss Ella Best, executive secretary of the A. N. A., denied the charges and called them unfair and ill advised.

Traffic Regulations for Car-Driving Amputees

Major Gen. G. B. Erskine, former head of the Retraining and Reemployment administration who has returned to the U. S. Marine Corps, wrote to George E. Keneipp, D. C. Director of Vehicles and Traffic, urging that some traffic restrictions be lifted for autodriving amputees. General Erskine stated: "It is my understanding that in both Seattle and New York the office of the Traffic Director, after due investigation, issues windshield cards and passbook cards of a similar nature, instructing traffic officers to exercise leniency in favor of automobiles driven by amputees in restricted areas."

Hearings on Water Pollution Control Bill

Open hearings will be held this month on a bill to provide for water pollution control activities in United States rivers. Chairman Revercomb of the Senate Public Works Committee said the measure was important enough to require public hearings. The bill is a bipartisan measure sponsored by Senator Barkley, Democrat of Kentucky, and Senator Taft, Republican of Ohio. It provides for federal aid for treatment works construction to prevent the discharge of pollution into rivers. The U. S. Public Health Service would survey specific problems of water pollution.

Gain in Births

The Census Bureau released preliminary figures estimating a total of 3,440,000 births in the United States last year, to boost the nation's population to an all time high of 141,000,000.

Commemorative Postage Stamp Will Honor Doctors of America

Postmaster General Robert E. Hannegan announced that a commemorative 3 cent postage stamp honoring the physicians of America will be issued by the Post Office Department next June 9. The special issue will come out on the hundredth anniversary of the founding of the American Medical Association. The public will be given details later of the place of sale and description of the stamp.

Encourage Employment of Nation's Disabled

The new National Association for Employment of the Handicapped will seek to carry on after the Retraining and Reemployment Administration closes June 30. The group elected Vice Admiral Ross T. McIntire, interim vice president. The former retraining administrator, Major Gen. G. B. Erskine, has resigned effective April 12 as administrator to return to the U. S. Marine Corps.

Medical Legislation

STATE LEGISLATION

Arizona

Bill Enacted.—H. 206, which has become chapter 130 of the laws of 1947, provides for the licensing, regulation and **inspection of hospitals** within the state.

Arkansas

Bill Enacted.—H. 299, which has become Act no. 326 of the Acts of 1947, provides that **all school employees** shall, biennially, produce a certificate issued by a regularly licensed physician or regularly constituted health authority certifying that such individual is free from any and all forms of contagious or infectious diseases, including tuberculosis, and that the status of such individual regarding tuberculosis has been determined by an x-ray examination.

California

Bill Passed.—S. 972, which passed the senate April 1, proposes, among other things, to authorize the state **board of chiropractic examiners** to approve chiropractic schools and colleges whose graduates may apply for licenses in the state and to set forth certain requirements which schools must meet in order to be eligible for such approval.

Colorado

Bill Passed.—H. 895, which passed the house March 28, proposes to appoint the Colorado State Department of Public Health as the sole agency for carrying out the purpose of the **federal hospital construction** act and to require the governor to appoint a state advisory hospital council.

Bill Enacted.—S. 453, which was approved March 24, amends the law relating to the **practice of chiropody** by defining the practice of chiropody as "the diagnosis and medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human toe, foot and leg, excepting any amputation and excepting the administration of an anesthetic other than local."

Delaware

Bill Passed.—H. 42, which passed the senate March 31, proposes to require all persons desiring to obtain a **marriage license** to obtain a certificate from a duly licensed physician showing that the applicant has undergone a standard serologic test for syphilis and is not infected with such disease in a stage which may become communicable to the marital partner.

Bill Enacted.—H. 9, which was approved March 25, amends the law relating to the **care of the blind** by requiring every health and social agency, attending or consulting physician or nurse to report to the Delaware Commission for the Blind, in writing, the name, age and residence of persons who are blind.

Idaho

Bill Enacted.—H. 219, which has become chapter 271 of the Laws of 1947, is an enabling act for the formation and **regulation of nonprofit corporations** organized to render medical, surgical and/or hospital service on a membership fee plan.

Illinois

Bill Introduced.—H. 315 proposes the enactment of a **hospital construction** act and authorizes the director of the state department of public health to direct the hospital construction program in the state.

Iowa

Bill Introduced.—S 469 proposes to require all physicians to report immediately to the health officer in writing the name, age and address of every person diagnosed as a case of **epilepsy** or similar disorders characterized by lapse of consciousness.

Bill Passed.—H. 465, which passed the house March 24, proposes a **hospital licensing law.**

Kansas

Bill Introduced.—H 83, **to amend the food and drug act,** proposes to limit the sale of aminopyrine, barbituric acid, pituitary, thyroid, sulfonmethane or their derivatives, to sale on prescriptions signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drugs

Bills Passed.—H 67, which passed the senate April 1, proposes the enactment of a **hospital licensing law.** H 399, which passed the senate April 1, proposes the enactment of a **hospital survey and construction act** requiring a survey of existing hospital facilities and the preparation of a program for the construction of additional needed facilities The proposal also provides for the appointment of an advisory hospital council and authorizes the application for and receipt of federal funds to assist in the survey and construction activities within the state.

Maine

Bill Enacted.—S. 293, which was approved April 4, 1947, authorizes the local health officer to provide annually for the **free vaccination** of all inhabitants within his jurisdiction and to provide for free inoculation against diphtheria and whooping cough of all children under 12 years of age

Maryland

Bills Passed.—H J R 16, which passed the house March 22 and the senate March 27, proposes the appointment of a commission to study **medicolegal psychiatry** in the state H 52, which passed the house March 29, proposes to amend the medical practice act by exempting therefrom persons treating human ills in accordance with the tenets of **Christian science,** even though an adequate charge for such service is paid H 83, which passed the senate March 29, proposes to **amend the chiropractic act** by among other things, defining chiropractic as "diagnosis, the location of disaligned or displaced vertebrae of the human spinal column the procedure preparatory to and the adjustment by hand of such misaligned or displaced vertebrae of the spinal column and its articulations, by any method not including the use of drugs, surgery or obstetrics, osteopathy, optometry or podiatry, or any branch of medicine for the purpose of relieving such interference and aiding in the restoration of health, providing that nothing herein contained shall be construed to prohibit the use of by any licensed Chiropractor of all necessary electrical, mechanical, dietetic and sanitary measures incident to the care of the human body, for the purpose of relieving such interference" H. 663, which passed the senate March 29, proposes to designate the **state board of health** as the sole agency to represent the state of Maryland in obtaining benefits under the federal hospital survey and construction act and proposes also to authorize the governor to appoint an advisory council on hospital construction S 209, which passed the house March 31, proposes the granting of **free scholarships** to the medical school of the University of Maryland S 358, which passed the senate March 27 and the house March 28, proposes to exempt from the medical practice act **Christian science practitioners** duly registered in the *Christian Science Journal* of the Christian Science Publishing Society, Boston.

Massachusetts

Bill Introduced.—H 1870, proposes the repeal of the existing law providing for the **licensing of maternity hospitals** and the enactment of new provisions which would require the licensing and regulating of all hospitals within the state

Bill Passed.—H 1919, which passed the house April 3, proposes that any person who was a resident of the commonwealth for a period of five years prior to July 1, 1941, who matriculated at any medical school in the commonwealth prior to said date and who since that time received a degree of doctor of medicine from such school shall **be eligible to apply for registration** as a qualified physician, shall be examined by the board of registration in medicine and shall be subject to all the provisions of the law relating to such eligibility and examination

Michigan

Bill Introduced.—S 201 proposes to authorize the state commissioner of health to regulate and promulgate rules and regulations controlling the **humane use of animals** for the diagnosis and treatment of human and animal diseases, the advancement of veterinary, dental, medical and biologic sciences and the testing and diagnosis, improvement and standardization of laboratory specimens, biologic products, pharmaceuticals and drugs The proposal would further require that no person, firm or corporation shall keep or use animals for experimental purposes unless registered to do so by the state commissioner of health.

Nevada

Bill Passed.—S 128, which passed the senate March 19, proposes that whoever experiments or operates in any manner whatsoever on any living **dog or cat** for any purpose other than to heal, cure or sterilize said dog or cat shall be punished by a fine of not less than $100 nor more than $500 or by imprisonment for not less than three months nor more than one year, or by both such fine and imprisonment.

Bills Enacted.—S 52, which has become chapter 230 of the Laws of 1947, amends the law relating to the state board of health by authorizing the state department to create a **division of preventive medical services,** together with such other divisions, subdivisions or bureaus as are and may be necessary for the prevention of disease, the prolongation of life and the promotion of the physical health and mental efficiency of the people of the state of Nevada. S 55, which has become chapter 98 of the Laws of 1917, amends the medical practice act by authorizing the state board of medical examiners, in its discretion, to issue permits to any properly qualified applicant to serve as **resident medical officer** in any hospital in Nevada subject to certain provisions. Such temporary licentiate would be authorized to practice medicine only within the confines of the hospital specified in his permit and the permit would in no case be in excess of one year, renewable at the discretion of the board of medical examiners

New Jersey

Bill Introduced.—S. 49, to amend the law relating to the **practice of chiropody,** redefines chiropody as follows: "the diagnosis of or the holding out of a right or ability to diagnose any ailment of the human foot, or the treatment thereof or the holding out of a right or ability to treat the same by any one or more of the following means: local medical, mechanical, minor surgical, manipulative and physiotherapeutic or the application of external medical or any other of the aforementioned means except minor surgical and local medical to the lower leg and ankle for the treatment of a foot ailment. not including, however, the treatment of tuberculosis, osteomyelitis, malignancies, syphilis, diabetes, tendon transplantations, bone resections, amputations, fractures, dislocations, the treatment of varicose veins by surgery or injection, the administration of anesthetics other than local, the use of radium, the use of x-rays except for diagnosis, or the treatment of congenital deformities by the use of a cutting instrument or electrosurgery. The term 'local medical' hereinbefore mentioned shall be construed to mean the prescription or use of a therapeutic agent or remedy where the action or reaction is intended for a localized area or part."

Bills Passed.—S. 66, which passed the house April 1, proposes to appoint the state department of institutions and agencies as the agency to receive federal funds to assist in a state **survey of hospitals** and the development of a state program for the construction of additional needed hospital facilities S 208, which passed the senate March 24, proposes to authorize the state department of health to purchase and distribute free, in accordance with rules of said department, **antibiotics** for use in preventing or treating communicable diseases.

New York

Bills Enacted.—S. 216, which has become chapter 523 of the Laws of 1947, amends the civil practice act by allowing admission in evidence of a **hospital bill bearing a certification** by the superintendent or other head of the hospital that the bill is correct, that each of the items shown was necessarily furnished and that the charge is fair and reasonable. A bill so admitted is prima facie evidence of the facts stated, subject to rebuttal by any party affected thereby. S. 1904, which has become chapter 408 of the Laws of 1947, requires any institution desiring to conduct scientific tests and **experiments on living animals** to be approved for that purpose by the state commissioner of health under such rules as the commissioner shall determine.

North Carolina

Bills Passed.—H. 623, which passed the house April 1, proposes to require laboratories making **serologic tests** to be certified by the North Carolina state board of health. H 744, which passed the senate April 2, proposes the enactment of a hospital licensing law and the appointment of a **state advisory council.**

Ohio

Bill Passed.—H. 294, which passed the house April 2, proposes to amend the law relating to the **practice of chiropody** by authorizing the state board of medical examiners to adopt rules and regulations permitting in the practice of chiropody the use of such drugs as are necessary to such practice.

Oklahoma

Bill Introduced.—H. 339 proposes the creation of a **commission on postmortem examinations.** Among other things the commission would appoint a chief medical examiner who shall be a pathologist, trained in legal medicine and licensed or eligible for licensure in Oklahoma as a doctor of medicine by the board of medical examiners and shall maintain a laboratory for the conduct of pathologic, bacteriologic and toxicologic investigations. The proposal would authorize the county medical examiner or the chief medical examiner to perform an autopsy whenever in his opinion it was advisable and in the best public interest. He may also cause an autopsy to be made on any person when death was caused from violence, or suddenly when in apparent good health, or when unattended by a physician, or in any suspicious or unnatural manner, or as the result of abortion or suspected abortion.

Oregon

Bill Passed.—S. 77, which passed the house March 29, proposes the repeal of existing laws requiring the licensing of **maternity hospitals** and certain other types of institutions and sanatoriums and the enactment of a new law requiring the licensing, inspecting and regulating of all hospitals and related institutions within the state.

Pennsylvania

Bills Introduced.—H. 667 proposes that all prescriptions for **narcotic drugs** shall be written upon printed forms prepared and issued by the department of health and that any person using such forms shall be able to account for every one of the forms issued to him at all times. S. 384 proposes that whoever experiments or directs, aids or assists in **experiments on a living dog** in any manner for the purpose of creating or inducing in or on the body of a living dog any disease, malady, disorder or any benign or malignant growth or who performs, directs, aids or assists in the performance of any operation on a living dog for any purpose other than the healing or curing of such dog of physical ailments or for the purpose of abating power of procreation is guilty of a misdemeanor and subject to various stated fines and imprisonment or both. S. 395 proposes to require any institution requiring for the effective carrying on of its scientific or educational activities **the use of live dogs and cats** to apply to the department of health for a license to obtain such dogs and cats from pounds in the jurisdiction. Such license would have to be renewed annually Nothing in the proposal, however, is to be construed as affecting the right of an institution to obtain dogs and cats from sources other than public pounds.

South Carolina

Bills Passed.—H. 353, which passed the house March 17, proposes an enabling act for the organization and operation of **nonprofit corporations** for the purpose of furnishing medical service at agreed rates through participating physicians. S. 254, which passed the senate March 25, proposes to authorize **osteopathic physicians** licensed in the state to certify birth and death certificates in the same manner as is now prescribed by law for other physicians.

South Dakota

Bill Enacted.—H. 18, which was approved March 10, requires the licensing of **chiropractic hospitals,** sanatoriums or related institutions by the board of chiropractic examiners.

Texas

Bill Passed.—H. 40, which passed the house April 1, proposes the creation of a Texas **Board of Chiropractic Examiners** and defines chiropractic to be "the employment of objective or subjective means, without use of drugs or surgery, for the purpose of ascertaining the alignment of the vertebrae of the human spine, and the practice of adjusting the vertebrae by hand to correct any subluxation or misalignment thereof."

Utah

Bills Enacted.—S 104, which was approved March 20, 1947, requires the licensing, inspecting and regulating of hospitals and the appointment of **a hospital advisory council.** S 151, which was approved March 20, is **a state hospital survey and construction act** which requires a survey of all hospital and public health center facilities in the state and the preparation of a program for the construction of additional needed facilities. The law requires the governor to appoint an advisory hospital council and authorizes the commissioner of the state department of health to apply for federal funds for assistance in either the survey or the construction program

Vermont

Bills Introduced.—H. 267 proposes the enactment of a **licensing law for hospitals,** sanatoriums, rest homes, nursing homes and related institutions. H. 317 proposes **a licensing law for hospitals,** sanatoriums, rest homes, nursing homes, homes for the reception of children and related institutions

Bills Passed.—S. 38, which passed the senate March 22, to amend the law relating to the **practice of osteopathy,** proposes to designate such practitioners as osteopathic physicians and surgeons, rather than practitioners of osteopathy, and to authorize such practitioners to issue certificates relative to the commitment of insane persons, and such reports and certificates should be accepted equally with the reports and certificates of physicians of other schools of medicine. The proposal would, in effect, authorize such physicians to have the same rights with respect to the rendering of medical service under the provisions of public health, welfare and assistance laws and regulations now or hereafter in force as are possessed by the regularly licensed physicians and surgeons in the state. The proposal would also require osteopaths to have preliminary training including one year of internship in a hospital approved by the board. S. 45,, which passed the senate March 28, proposes the enactment of a **hospital survey and construction act** requiring a survey of existing hospital facilities and the preparation of a program for the construction of additional needed facilities. The proposal also requires the appointment of an advisory hospital council and the acceptance of federal funds for assistance in state survey and construction activities.

Bill Enacted.—H. 164, which was approved April 1, provides an appropriation of $9,000 for the continued maintenance of the Vermont **Blood Plasma Bank.**

Wisconsin

Bills Introduced.—A. 319 proposes to prohibit the **sale of any dangerous drug** except on the prescription of a physician, dentist, chiropodist or veterinarian. The proposal defines dangerous drug to include any hypnotic drug (including acetylurea derivatives, barbituric acid or malonylurea derivatives, chloral, paraldehyde, phenylhydantoin derivatives, sulfonmethane derivatives, or any compounds or mixtures or preparations thereof that may be used for producing hypnotic effects); aminopyrine, amphetamine, desoxyephedrine, cinchophen, neocinchophen, diethylstilbestrol, ergot, cotton root, oils of croton, rue, savin or tansy, sulfanilamide or substituted sulfanilamides, thyroid, or compounds or mixtures of any such drugs. A. 382, to amend the law relating to **nonprofit sickness and care plans of medical societies,** proposes that no doctor licensed to practice under the state medical practice act shall be denied the right to participate in any other voluntary prepayment surgical, medical or sickness care plan that may be established by cooperatives or labor unions or other organized groups, or by any medical society having the powers and privileges conferred by this section and nothing contained in this section shall be construed to preclude the formation and establishment of such other plans by any one or more of said groups A. 421, to amend the law relating to **chiropractic,** proposes to require chiropractic applicants to have graduated from a school of chiropractic approved and recognized by the board of examiners. S. 421 proposes the creation of a state board of examiners in naturopathy and **defines naturopathy** as "the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the material methods or agencies of healing as taught by approved schools of naturopathy, said methods or agencies including dietetics, phytotherapy, vitamin or mineral or glandular food supplementations, irrigations, inhalations, external applications, physiotherapy and electrotherapy. The practice of naturopathy shall exclude the practice of medicine, surgery, obstetrics, osteopathy, chiropractic and the use of drugs. The practice of naturopathy shall exclude the treatment of cancer, tuberculosis, gonorrhea, syphilis, diphtheria, scarlet fever, typhoid fever, smallpox and fractures."

Miscellaneous

THE WORLD HEALTH ORGANIZATION

President Truman has sent to the Congress a suggested joint resolution providing for membership by the United States and participation in the World Health Organization. The President has said he is sure it will make a substantial contribution to world health conditions through the years; he considers it important that the United States join the World Health Organization as soon as possible. The resolution provides that the President is to designate from time to time to attend a specified session or sessions of the World Health Assembly not to exceed three delegates of the United States and such alternates as may be consistent with the rules of procedure of the World Health Assembly. One delegate is to be designated the chief delegate. Whenever the United States becomes entitled to designate a person to serve on the executive board of the World Health Organization, the President is to designate such a person; the one designated will be entitled to receive compensation at a rate not to exceed $12,000 per year for such period as the President may specify. Any officer of the United States is not entitled to receive compensation. The resolution also provides that the United States shall appropriate annually to the Department of State such sums as may be necessary to meet a share of the expenses of the organization and the expenses of the staff.

With the message from the President came a memorandum from the Department of State calling attention to the fact that the United States Senate expressed itself in favor of the early formation of such an organization on Dec. 20, 1945. Since that time an international health conference has been held, a constitution for a World Health Organization has been signed by sixty-one states and an Interim Commission has been established. The General Assembly of the United Nations adopted a resolution on Dec. 14, 1946 recommending that all members of the United Nations accept the constitution of the World Health Organization. The Department of State feels that such an international organization in the field of health is essential to attack diseases at their source, to prevent their spread and to raise the health level of peoples everywhere. The State Department points out that one of the purposes of the new organization is "the attainment by all people of the highest possible level of health."

The World Health Organization may assist states at their request in strengthening their national health services. This does not mean, however, that the organization will have in any way authority to interfere in the administration of health or medical care in any state. The chief functions of the organization will no doubt include the collection and improvement of worldwide disease statistics, the distribution of knowledge regarding health and medicine, the promotion of research and the continuation and further development of the highly important work done by the League of Nations in the standardization of drugs and biologic preparations. The constitution permits any government to reject any regulations that it finds unacceptable.

The structure of the World Health Organization provides for a health assembly and an executive board composed of eighteen persons designated by eighteen governments. The officials will include a director general and a secretariat. The constitution of the World Health Organization will come into force and the organization will be established when twenty-six members of the United Nations have notified the secretary general of the United Nations of their acceptance of the constitution. Thus far six members, including China, Canada, Iran, New Zealand, Syria and the United Kingdom, have taken the necessary action.

Medical Economics

MEDICAL GROUPS IN THE UNITED STATES, 1946

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

The percentage of practicing physicians engaged in group practice in the United States in 1946 was approximately the same, 2 per cent, as in 1940. This conclusion is based on a comparison of studies made in 1940 by the American Medical Association and in 1946 by the U. S. Public Health Service. Under the direction of Dr. G. Halsey Hunt, Senior Surgeon, the U. S. Public Health Service is conducting a study of group practice a preliminary report of which will be published in the *New England Journal of Medicine* (in press). Just released in connection with the major report is a list of the groups which replied to a questionnaire sent out last summer. This list, "Medical Groups in the United States, 1946" (61 pages, mimeographed), was used in a comparison with the 1940 publication "Group Medical Practice," prepared by Dr. Roscoe G. Leland of the Bureau of Medical Economics. We have made a state by state comparison with respect to the number of groups and the number of physicians in groups; the number of groups in each state was expressed as a percentage of the number of groups in the nation; the number of groups in existence in 1940 which are not now in existence was tabulated; the percentage distribution of physicians in active practice in 1946 (whether in group or other types of practice) was estimated. Our analysis indicates that approximately 2 per cent of the practicing physicians are and were full time physicians on the staffs of groups as shown in the 1940 (2,093) and 1946 (3,275) studies.

The table shown herewith summarizes the comparisons by nine groups of states. The data by states (not shown) indicate that group practice is relatively prominent in Minnesota, California and Montana; contrariwise, it is not very prevalent in New York, New Jersey and Pennsylvania. New York has only one fortieth of the groups in the entire nation but approximately one sixth of all practicing physicians in the nation. Dr. Hunt lists no groups in Maine, Connecticut and Rhode Island. The items for the states are reflected in the totals for the groups of states shown in the table.

Dr. Hunt's list of 407 comprises groups classified as private, industrial, consumer, hospital, medical school or government. The following directory information is given: name, street address, medical director, business manager, primary activity, fields covered and number of physicians, nurses and dentists. The author warns the reader that there are doubtless some omissions from this list because most but not all of the known groups replied to the author's questionnaire. Except for the omission of the Lahey Clinic of Boston, it appears to me that this list is quite comprehensive.

The length of this list is due to the intention of the author to include all doubtful cases. "The only qualifications required of a group for inclusion here are, first, that it have some sort of formal organization and, second, that it have at least three full time physician members." The definition of group practice as developed by the Bureau of Medical Economics in its 1940 report would not include all these 407 groups. The Bureau's definition specified that:

1. There must be at least three physician members.
2. The receipts from medical practice must have been pooled in some manner and then redistributed to the members according to some previously arranged plan.
3. "Closed staff" hospitals were not included unless the members of the staff pooled the income received for services outside the hospital.
4. Purely "diagnostic groups" which receive only referred cases were excluded.
5. "Industrial" groups which furnish medical services to a single industry and thus to only a limited group of the general population were omitted.

Until our Bureau of Medical Economic Research completes its revision of the 1940 study by Dr. Leland we cannot estimate the number of existing groups which comply with the Bureau's 1940 definition. The 1940 report of the Bureau listed 339 groups; only 219 of these appear in Dr. Hunt's list. Apparently 120 groups were dissolved during the six years. Similarly a comparison between our Bureau's 1932 and 1940 lists showed that 63 of the 239 groups on the 1932 list had been discontinued during that eight year interval. This is evidence that the mortality rate of medical groups is significant and should be considered carefully in any study of group practice or in comparing the increase or decrease in the number of groups from time to time. It is important to know what groups organize and fail in a short time and what groups maintain themselves and their organization over a significant number of years. An additional factor of group practice which should be considered is the partnership aspect, which often necessitates complete reorganization of a group in the event of death or withdrawal of one of the partners.

The U. S. Public Health Service has made a good beginning in its study of group medical practice, and the preliminary list of 407 groups should serve as a useful directory.

Medical Groups in Geographic Divisions of the United States 1940 (A. M. A.) and 1946 (U. S. P. H. S.) Surveys

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Aero Medical Association of the United States, Atlantic City, June 4-6. Dr. David S. Brachman, 1016 Dime Bldg., Detroit 26, Secretary.

American Association for Thoracic Surgery, St. Louis, May 28-30. Dr. Richard H. Meade Jr., 55 E. Washington St., Chicago 2, Secretary.

American Association of Genito-Urinary Surgeons, Absecon, N. J., June 4-6. Dr. Charles C. Higgins, 2020 E. 93d St., Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Buffalo, N. Y., Statler Hotel, April 26-May 4. Dr. Frederick W. Slobe, 28 E. Jackson Blvd., Chicago 4, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, May 16-17. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland 6, Secretary.

American Association of Plastic Surgeons, Nashville, Tenn., May 5-6 and Memphis, Tenn., May 7-8. Dr. Frederick A. Figi, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Association of the History of Medicine, Cleveland, May 25-26. Dr. Howard Dittrick, 2020 E. 93d St., Cleveland 6, Secretary.

American Association on Mental Deficiency, St. Paul, Minn., May 28-31. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American College of Allergists, Atlantic City, Hotel Senator, June 6-8. Dr. Fred W. Wittich, 401 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Chest Physicians, Atlantic City, June 5-8. Mr. Murray Kornfeld, 500 N. Dearborn St., Chicago 10, Executive Secretary.

American College of Physicians, Chicago, April 28-May 2. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Secretary.

American College of Radiology, Atlantic City, June 6-7. Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Dermatological Association, Murray Bay, Quebec, Can., June 1-5. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Wis., Secretary.

American Geriatrics Society, Atlantic City, Hotel Brighton, June 5-7. Dr. Malford W. Thewlis, 25 Mechanic St., Wakefield, R. I., Secretary.

American Heart Association, Atlantic City, Hotel President, June 6-7. Dr. Howard B. Sprague, 50 W. 50th St., New York, Secretary.

American Laryngological Association, St. Louis, April 23-24. Dr. Arthur W. Proetz, 12 Westmoreland Place, St. Louis 8, Secretary.

American Laryngological, Rhinological and Otological Society, St. Louis, April 25-26. Dr. C. Stewart Nash, 288 Alexander St., Rochester 7, N. Y., Secretary.

American Medical Women's Association, Atlantic City, June 7-8. Dr. Helen F. Schrack, 216 N. Fifth St., Camden, N. J., Secretary.

American Neisserian Medical Society, Atlantic City, Marlborough-Blenheim Hotel, June 8. Dr. William L. Fleming, 750 Harrison Ave., Boston, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Otological Society, St. Louis, April 21-22. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

American Pediatric Society, Stockbridge, Mass., May 13-15. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Chicago, May 18-22. Dr. Maurice Visscher, University of Minnesota, Minneapolis, Secretary.

American Proctologic Society, Atlantic City, June 7-8. Dr. Harry E. Bacon, 2031 Locust St., Philadelphia 3, Secretary.

American Psychiatric Association, New York, Hotel Pennsylvania, May 19-23. Dr. Leo H. Bartemeier, General Motors Bldg., Detroit, Secretary.

American Radium Society, Atlantic City, June 8. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Society for Clinical Investigation, Atlantic City, Chalfonte-Haddon Hall, May 5. Dr. Eugene A. Stead Jr., Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Chicago, May 19-23. Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Chicago, May 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Va., Secretary.

American Society for Research in Psychosomatic Problems, Atlantic City, May 3-4. Dr. Edwin G. Zabriskie, 714 Madison Ave., New York 21, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Shand, June 7-8. Dr. John O. Haman, 490 Post St., San Francisco 2, Secretary.

American Society of Biological Chemists, Chicago, May 18-22. Dr. Otto A. Bessey, Public Health Research Institute, New York 9, Secretary.

American Society of Clinical Pathologists, Atlantic City, June 4-8. Dr. Alfred S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Therapeutic Society, Atlantic City, Chalfonte Hotel, June 6-7. Dr. Oscar B. Hunter, 1835 I St., N. W., Washington 6, D. C., Secretary.

Arizona State Medical Association, Tucson, May 7-10. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 6-7. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Association of American Physicians, Atlantic City, May 6-7. Dr. Joseph T. Wearn, Lakeside Hospital, Cleveland 6, Secretary.

California Medical Association, Los Angeles, Hotel Biltmore, April 30-May 3. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, New Haven, April 28-30. Dr. Creighton Barker, 258 Church St., New Haven 10, Secretary.

Federation of American Societies for Experimental Biology, Chicago, May 18-22. Dr. William H. Chambers, 1300 York Ave., New York 21, Secretary.

Florida Medical Association, Miami, April 20-23. Dr. Robert B. McIver, P. O. Box 1018, Jacksonville, Secretary.

Georgia, Medical Association of, Augusta, Bon Air Hotel, April 22-25. Dr. Edgar D. Shanks, 478 Peachtree St. N. E., Atlanta, Secretary.

Hawaii Territorial Medical Association, Lihue, Kauai, May 1-4. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu 53, Secretary.

Illinois State Medical Society, Chicago, Palmer House, May 12-14. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.

Kansas Medical Society, Topeka, May 12-15. Dr. John M. Porter, 512 New England Bldg., Topeka, Secretary.

Louisiana-Mississippi Ophthalmological and Otolaryngological Society, Biloxi, Miss., Buena Vista Hotel, May 5. Dr. Edley H. Jones, 1301 Washington St., Vicksburg, Miss., Secretary.

Louisiana State Medical Society, New Orleans, May 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 22-23. Dr. W. Houston Toulson, 1211 Cathedral St., Baltimore 29, Secretary.

Massachusetts Medical Society, Boston, Hotel Statler, May 20-22. Mr. Robert St. B. Boyd, 8 Fenway, Boston 15, Executive Secretary.

Medical Library Association, Cleveland, Wade Park Manor, May 27-29. Miss Heath Babcock, New York State Medical Library, Albany 1, New York, Secretary.

Mississippi State Medical Association, Biloxi, May 6-8. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

National Gastroenterological Association, Atlantic City, June 4-6. Dr. G. Randolph Manning, Room 319, 1819 Broadway, New York, Secretary.

Nebraska State Medical Association, Omaha, April 28-May 1. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New Jersey, Medical Society of, Atlantic City, Haddon Hall, April 22-24. Dr. Alfred Stahl, 160 Lincoln Ave., Newark 4, Secretary.

New Mexico Medical Society, Albuquerque, April 30-May 3. Dr. H. L. January, 221 West Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, May 5-9. Dr. Walter P. Anderton, 292 Madison Avenue, New York 19, Secretary.

North Carolina, Medical Society of the State of, Virginia Beach, Va., Cavalier Hotel, May 12-14. Dr. Roscoe D. McMillan, P. O. Box 232, Red Springs, Secretary.

North Dakota State Medical Association, Fargo, May 25-27. Dr. L. W. Larson, 221 Fifth St., Bismarck, Secretary.

Ohio State Medical Association, Cleveland, May 6-8. Mr. Charles S. Nelson, 79 E. State St., Columbus 15, Executive Secretary.

Oklahoma State Medical Association, Tulsa, Mayo Hotel, May 14-16. Mr. R. H. Graham, 210 Plaza Court Bldg., Oklahoma City, Executive Secretary.

Rhode Island Medical Society, Providence, May 14-15. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.

Society of American Bacteriologists, Philadelphia, May 13-16. Dr. Leland W. Parr, 1335 H St. N. W., Washington 5, D. C., Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Texas, State Medical Association of, Dallas, Adolphus Hotel, May 5-8. Dr. Holman Taylor, 1404 W. El Paso St., Fort Worth 3, Secretary.

United States-Mexico Border Public Health Association, San Diego, California, and Tijuana, Mexico, May 6-8. Dr. James A. Grider Jr., 151 U. S. Court House, El Paso, Texas, Secretary.

West Virginia Medical Association, Charleston, May 12-14. Mr. Charles Lively, 1031 Quarrier St., Charleston 24, Secretary.

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Colonel Edmund Horgan

The Legion of Merit has been awarded to Col. Edmund Horgan, M. C., A. U. S., of Delaplane, Va., who performed exceptionally meritorious services at Foster General Hospital and later at Brooke General Hospital from January 1943 to March 1946. As noted in the citation, in his capacity as chief of the surgical service he was responsible for the organization and the close supervision of all personnel concerned with surgery at these two hospitals. The prompt and efficient handling of serious medical and surgical cases under his care insured completeness of treatment and the attainment of maximum benefits. His stimulation of higher attainment of younger surgeons and his thoroughness of technical training have reflected great credit on him and on the Medical Department. Dr. Horgan graduated from George Washington University School of Medicine in 1908 and entered the military service March 2, 1943.

Colonel Robert H. Lowry

The Legion of Merit has been awarded to Col. Robert H. Lowry, M. C., U. S. Army, of Washington, D. C., who served with distinction as commanding officer, general dispensary, and as surgeon, Military District of Washington, from February 1943 to August 1946. The superior health record established for the military district was credited by the citation for his successful solution of many problems incident to continued changes in medical personnel, supply and administration. Through his energetic efforts, superior leadership and outstanding professional skill, Colonel Lowry was primarily responsible for the high standards of operating efficiency achieved and maintained in the dispensary throughout an extended and crucial period. Dr. Lowry graduated from Rush Medical College in 1914 and entered the military service July 6, 1917.

Colonel Earl R. Denny

The Legion of Merit was recently awarded to Col. Earl R. Denny, M. C., A. U. S., of Tulsa, Okla., who, according to the citation, rendered exceptionally outstanding and meritorious service as chief of the medical service at Gardiner General Hospital, Chicago, from October 1943 to February 1946. His energetic and untiring efforts in the care and treatment of his patients, combined with his studies in the use of penicillin, resulted in the recovery of many extremely critical cases. His work in this field was a most laudable contribution to the efforts of the Medical Corps. Dr. Denny, who has also been awarded the Army Commendation Ribbon, graduated from Indiana University School of Medicine in 1925 and entered the service on May 7, 1942.

Colonel Howard E. Boucher

The Legion of Merit was recently awarded to Col. Howard E. Boucher, M. C., A. U. S., of Columbus, Ohio, for meritorious service during the period September 1940-January 1946 in a position requiring exceptional skill and ability at state headquarters, Selective Service System, Columbus, Ohio. Dr. Boucher graduated from Ohio State University College of Medicine in 1910 and entered the service Oct. 18, 1940.

Colonel Paul I. Robinson

The Oak Leaf Cluster to the Legion of Merit was recently awarded to Col. Paul I. Robinson, M. C., A. U. S. The citation read as follows: "Colonel Paul I. Robinson, successively as chief of various divisions of the Supply Service, Surgeon General's Office, was directly responsible for the evolution of a superior state of preparedness in Medical Department material lanning, from December 1941 to January 1945. His foresight and the quality of his efforts resulted in plans developed in such practical detail that they were placed in operation without deviation and proved to be complete and adequate for highly successful application." Dr. Robinson graduated from Washington University School of Medicine in 1928 and entered the service Aug. 1, 1929.

Lieutenant Colonel Robert C. Gaskill

The Legion of Merit has been awarded to Lieut. Col. Robert C. Gaskill, M. C., U. S. Army. The citation stated that he performed exceptionally meritorious service from December 1941 to April 1942 on Luzon, Philippine Islands. With limited supplies, personnel and equipment, he supervised the administration of medical care so that despite the tropical climate, malnutrition and conditions of combat the medical service successfully maintained a high combat effectiveness among the troops. Dr. Gaskill graduated from the University of Texas Medical School in 1929 and entered the military service July 1, 1929.

Lieutenant Colonel Joseph E. Smadel

The United States of America Typhus Commission Medal has been awarded to Lieut. Col. Joseph E. Smadel, M. C., A. U. S., of Washington, D. C. The citation recalls that he rendered exceptionally meritorious service in the investigation of typhus fever during the period June 1943 to March 1945. First as chief of the virus division, First Medical General Laboratory, in the European Theater of Operations, and later as chief of the division of virus and rickettsial diseases at the Army Medical School, Washington, D. C., he provided special laboratory and biologic supply services which were essential to the work of the United States of America Typhus Commission and to other organizations of the Army. By his original investigations he advanced the knowledge of rickettsial infections, carried on new studies of the chemotherapy of typhus and developed a type of vaccine against scrub typhus. He contributed to practical typhus control and to the advancement of medical science. Dr. Smadel graduated from Washington University School of Medicine in St. Louis and entered the military service Aug. 17, 1942.

Lieutenant Colonel Brittain F. Payne

The Army Commendation Ribbon was recently awarded to Lieut. Col. Brittain Ford Payne, M. C., A. U. S., of New York, for the part he played "in making the course in ophthalmology at the AAF School of Aviation Medicine outstanding in every respect." Said the citation addressed to Lieutenant Colonel Payne "Your lectures were incomparably thorough and concise. The meticulous care displayed by you in the preparation of ophthalmological training aids made this complex highly technical specialty more easily and thoroughly understood by your students. You have displayed unusual devotion to duty, initiative and loyalty to your assignment." Dr. Payne graduated from the University of Texas Medical Branch, Galveston, and entered the service Nov. 22, 1942.

Captain Branch Craige Jr.

The Army Commendation Ribbon has been awarded to Capt. Branch Craige Jr., M. C., A. U. S., of El Paso, Texas, whose service with the Medical Department was stated in the citation to have been exceptional when compared with others of the same grade or similar position. Captain Craige was commended for his outstanding contribution as officer in charge of the Clinical Research Unit, organized during the Malarial Research work at Stateville Penitentiary, Joliet, Ill., through the joint effort of the University of Chicago and the Office of Scientific Research and Development for March 1945 to March 1946. Dr. Craige graduated from Harvard Medical School in 1939 and entered the military service in July 1943.

NAVY

ACTIVE DUTY FOR RESERVE OFFICERS

Naval Air Reserve Training Command, Naval Air Station, Glenview, Ill., announces that opportunities for medical reserve officers to return to active duty at one of many air stations in this command are available. As of February 25 a billet was available at Glenview for a commander flight surgeon. Government quarters are available at several of the stations. Flight surgeons receive duty involving flying which entitles them to flight pay. Individuals may terminate their active duty at any time. Reserve medical officers and pharmacists interested should write to the Bureau of Naval Personnel via the Chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill. Personnel are desired in ranks not above that of commander in the medical corps; however, captains may apply for duty in their rank requesting waiver.

MEDICAL ASPECTS OF ATOMIC WARFARE

At a meeting of medical officers, Naval Medical Center, Bethesda, Md., March 27, the subject of discussion was the medical aspects of atomic warfare, and the speakers were Dr. Shields Warren, professor of pathology, Harvard Medical School, Boston, and Capt. R. Harold Draeger (MC), U.S.N.R. Dr. Warren, formerly captain in the Naval Medical Reserve Corps, was executive officer of the Naval Medical Reserve section at the Bikini tests and Captain Draeger was officer in charge of the section directing all animal and biologic observations at Operation Crossroads. Army, Public Health, Veterans Administration and civilian doctors of the District of Columbia and Montgomery County were invited. Refreshments were served at the conclusion of the program, which was the seventh of a series sponsored by the Naval Medical School.

NAVY AWARDS AND COMMENDATIONS

Captain Ralph E. Fielding

The Bronze Star Medal and a Gold Star in lieu of a second Bronze Star were recently awarded to Comdr. (now Capt.) Ralph E. Fielding (MC), U.S.N. The citations read in part as follows: For meritorious service as medical officer on the staff of the Commander Third Amphibious Force from July 15, 1943 to March 31, 1944, when the force carried out amphibious operations for the successful seizure of Vella La Vella, Treasury, Cape Torokina on Bougainville, Green and Emirau Islands. Throughout these engagements he displayed exceptional skill in preparing and directing effective measures for the care of the wounded. His direction of the prompt evacuation and immediate administration of surgical treatment resulted in the saving of many lives.

For distinguishing himself by meritorious service as medical officer on the staff of an amphibious task force from April 1, 1944 to April 17, 1945, when amphibious operations were carried out which resulted in the seizure of islands of the Palau Group, and in the execution of the initial landings on Leyte and Luzon Islands, Philippine Islands. Plans for the evacuation and treatment of the wounded in these three operations were prepared by Commander Fielding; he participated in the operations against the enemy on Leyte and Luzon islands, during which, although subjected to numerous enemy air attacks and to threats of attack by the Japanese fleet, he capably directed the prompt evacuation and hospitalization of casualties. Throughout these periods his initiative, devotion to duty and thorough knowledge of military medicine were largely instrumental in the alleviation of much suffering and were in keeping with the best traditions of the naval service. Dr. Fielding graduated from Harvard Medical School in 1928 and began his service in the U. S. Navy July 5, 1928.

Commander Paul Harry Morton

The Air Medal has been awarded to Comdr. Paul Harry Morton (MC), U.S.N., for meritorious achievement as senior flight surgeon in Headquarters Squadron, Fleet Air Wing Seven, during operations against the enemy in the Bay of Biscay and the English Channel from Oct. 1, 1944 to May 1, 1945. The citation related that Commander (then Lieutenant Commander) Morton, participating in numerous operational flights during this period, contributed to the success of his air wing in providing protection for the supply lines in the English Channel during the advance of Allied armies through occupied France. He aided in the improvement of the physical and mental standards of United States naval aviators and plane crews. His tireless devotion to duty was in keeping with the highest traditions of the United States Naval Service. Dr. Morton graduated from Jefferson Medical College of Philadelphia in 1938 and entered the military service July 19, 1938.

MISCELLANEOUS

SALE OF SURPLUS MEDICAL SUPPLIES

From the various regional and subregional offices of the War Assets Administration notices have been received of the following sales of government surplus medical supplies in the purchase of which physicians who are veterans have certain priorities:

Columbus, Ohio, Subregional Office, 4300 East Fifth Avenue, bids open April 24. Among the equipment on sale are instruments, dressings and water sterilizers.

New York Regional Office, 37 Broadway, New York; bids received until April 23. Sale of bandages, case fitting, eyeglass, gas mask; first aid packets; rubber catheters; kit: water testing screening for chemical warfare agents; molybdenum, bone plates; surgical face masks, retractors and bone screws. Some of this property is at the Medical Supply Depot, Binghamton, N. Y., or New York Port of Embarkation, Brooklyn, Port Johnston, Bayonne, N. J., and Warehouse X-066, Corona, Long Island.

San Francisco District Disposal Office, 33 Berry Street, San Francisco 7, bids open on May 1. Large quantities of atabrine ampules and tablets for sale, some at the Stockton General Depot, Stockton, Calif., some at the Naval Medical Supply Depot, Oakland, and some at the San Francisco Medical Depot, 1855 Folsom Street, San Francisco.

Kansas City Regional Office, 95th and Troost, Kansas City, Mo.; sale closes April 21. Among items for sale are stretchers, litters, anatomical charts, portable emergency operating lamps, thermometers, sulfapyridine tablets, patients' chairs with head rest, hospital and utensil sterilizers (used), surgical instruments (used).

Birmingham Regional Office, 1955 North Fiftieth Street, Birmingham, Ala.; sale now is on a first come first serve basis. Among items for sale are dissecting scissors, bone chisels, bone clamps, curets, surgical knives, retractors, trephine sets, bone drills, dilators, bone forceps, sterilizers, distilling apparatus, surgical needles, food carts, operating lamps, luer syringes, catheters, oxygen tents.

Louisville Regional Office, 412 West Market Street, Louisville 2, Ky.; bids opened April 28. Among items for sale are large quantities of catgut, silkworm, braided silk, nylon, horsehair and kangaroo sutures and wound clips.

Indianapolis Subregional Office, 2005 Northwestern Avenue, Indianapolis; bids to be opened April 29. Among articles for sale are whirlpool baths, eye magnet, clinical lamp, tantalum foil, Thomas splints. The bids to another sale under the jurisdiction of this subregional office will be opened April 28 and include, among other things, gauze bandages, food carts, hospital screens, crutches and first aid kits.

Seattle Regional Office, 1409 Second Avenue, Seattle; bids received until 11 a. m., April 22. Among the items for sale are blood transfusion apparatus, dermatome cement, rubber blankets and bedside tables.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Annals of Western Medicine and Surgery.—This new monthly journal began publication in March under the auspices of the Los Angeles County Medical Association. With an initial circulation of 7,500 copies it will serve three medical schools and more than 5,000 physicians in Los Angeles County alone. Contributions of fairly general rather than technical interest are preferred, as the majority of those who receive the *Annals* are engaged in general practice. The need for such a publication has become apparent since the *Southern California Practitioner*, founded in 1886, was discontinued in 1943 for lack of financial support. Dr. Edmund T. Remmen, Los Angeles, is the editor.

Organize Emergency Centers.—The board of supervisors of Los Angeles County has ordered to be organized a chain of seventy-one emergency hospital and ambulance centers, which would be responsible for transporting injured persons to regular hospitals nearest the scenes of accidents. Incorporated communities in the county were urged to pay for the services given persons injured within their boundaries through contracts with the county. Private ambulance operators and hospitals are expected to furnish the personnel and equipment for this work under county contracts. The cost of the program, including installations, is estimated at about $70,000 for the first year, according to the Los Angeles *Times*. This plan is expected to clear up the confusion that exists when injured persons have been left for some time where an accident occurs because of disputes as to which community should assume responsibility in caring for them.

Annual State Medical Meeting.—The seventy-sixth annual session of the California Medical Association will meet April 30-May 3 at the Biltmore Hotel, Los Angeles, under the presidency of Dr. Samuel J. McClendon, San Diego. In addition to numerous presentations by Californians, the following from other states will speak:

Dr. Ashley W. Oughterson, New York, The Diagnostic Problem in Gastrointestinal Cancer.
Dr. Albert M. Snell, Rochester, Minn., Infectious (Viral) Hepatitis and the Public Health.
Dr. Hobart A. Reimann, Philadelphia, Periodic Diseases.

The fourteen sections have arranged extensive programs to be presented by members of the association. The Section on General Medicine will have a panel discussion of virus diseases Wednesday, another on diseases of the stomach Thursday, and a symposium on "What's New" on Friday. There will be a clinical pathologic conference Friday afternoon. The Section on General Surgery will hold a symposium on back pain Thursday afternoon and a panel discussion on breast tumors Friday morning. A symposium on arthritis and another on urinary tract infections are part of the program of the Section on General Practice. The Woman's Auxiliary will also meet at the Biltmore April 30 to May 2.

CONNECTICUT

Cancer Consultative Clinic Opened.—The first cancer consultative clinic sponsored by the Connecticut Cancer Society opened January 28 with five physicians in attendance. The clinic, which will serve persons throughout the state, is open Tuesday mornings from 9 to 12 at McCook Memorial Hospital, 2 Holcomb Avenue, Hartford.

Rehabilitation.—At the first public meeting of the newly organized Connecticut Rehabilitation Association, held recently in New Haven, Dr. Howard A. Rusk, head, department of rehabilitation and physical medicine, New York University College of Medicine, and associate editor of the New York *Times*, spoke on "Restoration of the Disabled to Useful Living."

Commission on Alcoholism.—The former Yale School Plan Clinics have been taken over by the commission on alcoholism of the state of Connecticut. The commission was created in 1945 by the general assembly along with a state fund for inebriates and was charged with planning for outpatient and inpatient care and treatment and detention of patients suffering with alcoholism. Dr. Theodore P. Sohler, who has been at the Psychiatric Clinic of Yale School of Medicine at New Haven Hospital as physician in charge, has been added to the staff as a full time clinical psychiatrist. Additional clinics or facilities are to be set up in the major population centers of the state. Dr. Dudley P. Miller, New Haven, executive director of the commission, said he hoped to establish relations with private, municipal and state social agencies, hospitals and courts whereby the work of the commission and the agencies may be of mutual benefit in caring for alcoholic addicts.

GEORGIA

Prize to Encourage Writing.—An annual prize of $100 for the best paper or case report by a younger member of the Fulton County Medical Society will be given by Drs. Walter W. Daniel and John C. Ivey, Atlanta. The recipient must, at the time he makes his presentation, have been a member of the society for not more than five years, provided he joined within six months after completing his hospital training. The award will be made at the annual meeting each year.

Annual State Medical Meeting.—The Medical Asssociation of Georgia will hold its ninety-seventh annual session April 22-25 in Augusta at the Bon Air Hotel under the presidency of Dr. Ralph H. Chaney, Augusta. The house of delegates will meet Tuesday afternoon and evening. At the scientific sessions beginning Wednesday Dr. Edward L. Bortz, Philadelphia, President-Elect of the American Medical Association, will deliver the Abner Wellborn Calhoun Lecture. Among the other speakers will be:

Dr. Max M. Peet, Ann Arbor, Mich., Bilateral Supradiaphragmatic Splanchnicectomy in the Treatment of Arterial Hypertension.
Dr. Howard A. Howe, Baltimore, How Is Poliomyelitis to Be Controlled?
Dr. Clarence A. Good Jr., Rochester, Minn., Roentgenologic Diagnosis of Tumors of the Small Intestine.

The Woman's Auxiliary will hold its annual convention April 22-24. The annual banquet and dance will be Thursday at 7:30 p. m. Annual dinners for the alumni of Emory University School of Medicine, Atlanta, and the University of Georgia School of Medicine, Augusta, are scheduled for Wednesday night. Special societies having luncheons during the sessions are the Georgia Eye, Ear, Nose and Throat Society, the American Medical Women's Association, the Georgia Pediatric Society and the Georgia Roentgenological Society.

ILLINOIS

Typhoid Vaccine Given Following Flood.—About 1,000 residents of Chicago Heights and Robbins were given typhoid vaccine April 8 following the preceding week's flood in the southern and western parts of Cook County. Dr. Edward A. Piszczek, county health officer, announced that a series of three weekly injections will be offered to some 6,000 persons.

Appoint Superintendent of Sanatorium.—Dr. Robinson Bosworth, East St. Louis, former president of the National Tuberculosis Association, has signed a three year contract as medical director and superintendent of the Rock Island County Sanatorium. He was formerly employed as medical director at the Rockford sanatorium and in 1937 was employed in St. Clair County, where he built the new sanatorium and served as medical director until 1946. Dr. Bosworth received his M.D. degree at Jefferson Medical College of Philadelphia in 1905.

Health Departments Consolidate.—Election returns of April 1 recorded a vote in Adams County for consolidation of the Quincy Public Health District with the Adams County Public Health Department by a plurality larger than any received by candidates for office, according to Dr. Roland R. Cross, Springfield, state director of public health. Consolidation approved by vote was a necessary step in securing an over-all public health service for Adams County including the city of Quincy. The Adams County Board of Health will assume jurisdiction over the Quincy area March 31, 1948.

Chicago

Society News.—At the annual meeting of the Chicago Dermatological Society Drs. Francis W. Lynch, St. Paul, was elected president, Stephen Rothman vice president and Leonard F. Weber secretary-treasurer.

The Zeit Memorial Lecture.—The Frederick Robert Zeit Memorial Lecture will be delivered on May 15 at 4 p. m. in Thorne Hall by Dr. W. Barry Wood Jr., Busch professor of Medicine, Washington University School of Medicine, St. Louis, on "Mechanisms of Recovery in Bacterial Pneumonia." The lecture is sponsored by the Xi chapter of Alpha Kappa Kappa, Northwestern University Medical School, Chicago, in honor of the late Dr. Zeit, former professor of pathology.

INDIANA

Personal.—Rolla N. Harger, Ph.D., professor of biochemistry and toxicology in the Indiana Universtiy School of Medicine, Bloomington-Indianapolis, has joined the staff of the Indiana Bureau of Industrial Hygiene as consultant on toxicology.

Diphtheria Prevention in Sullivan County.—In 1937 the Sullivan County Medical Society began a program of immunization against diphtheria in the county to continue for ten years or longer if necessary to evaluate the results. During the past ten years more than 9,000 persons, or one third of the population of the county, have been given diphtheria toxoid immunization. Most of the counties bordering on Sullivan County have had mild epidemics of diphtheria since 1936, but only 4 cases have been reported in Sullivan, 3 in 1938 and 1 in 1944, all in families that had not been immunized. In the previous decade 1927 to 1936 Sullivan County reported 109 cases of diphtheria with 19 deaths. In the decade ended with 1945 there were 8,053 cases of diphtheria, with 659 deaths reported in the entire state of Indiana.

MASSACHUSETTS

Diphtheria in Boston.—The health commissioner of Boston, Dr. John H. Cauley, reports that the number of cases of diphtheria in Boston has continued to increase steadily and that immediate action must be taken to control the disease. In the six years preceding 1946 there were 179 cases with 10 deaths and in 1946 there were 157 with 10 deaths. During January and February 66 cases developed in Boston, the greatest number that has occurred in any two months during the last fifteen years. A citywide campaign for diphtheria immunization has been conducted. Physicians are urged to emphasize the need for immunization and booster doses. The health department advocated that all children be taken to their own physician or, where not practical, to clinics provided by the health department and school authorities. Toxoid is available free of charge to all city culture stations.

Public Health Appointments.—Dr. Eugene R. Sullivan, Milton, has been appointed an assistant director, Division of Biologic Laboratories, Massachusetts Department of Public Health. Dr. Sullivan, recently a lieutenant colonel in the U. S. Army Medical Corps, served three years overseas as chief of laboratories, Sixth General Hospital, as consultant on blood and blood transfusions for the North African and Mediterranean theaters of operation and on a board for the study of the treatment of the seriously wounded. Formerly Dr. Sullivan held positions at Harvard Medical School, the Massachusetts General Hospital and the University of Michigan School of Public Health.——Dr. Salvatore R. Traina, Boston, former command surgeon of the Seventh Air Service Area Command in Tokyo, is now serving as physician in charge of the mobile unit of the State Blood Donor Program, Division of Biologic Laboratories, Massachusetts Department of Public Health. Dr. Traina served for twenty-eight months in the Asiatic-Pacific theater, being discharged with the rank of major.——Dr. Barbara F. Carter, Boston, has been appointed assistant district health officer of the North Metropolitan District, Massachusetts Department of Public Health. Dr. Carter formerly was house officer and assistant resident, Third Medical Service, Boston City Hospital.

NEBRASKA

Annual State Medical Meeting.—The seventy-ninth annual convention of the Nebraska State Medical Association will be held April 28-May 1 at the Hotel Paxton, Omaha, under the presidency of Dr. George E. Charlton, Norfolk. As a departure from the customary scientific program, afternoons will be devoted to informal panel discussions during which members will have an opportunity to present individual problems to guest speakers. During the morning sessions formal lectures will be delivered. The guest speakers will be:

Dr. Frank R. Peterson, Iowa City, Cancers in Small Bowel.
Dr. Willis M. Fowler, Iowa City, New Agents in Treatment of Blood Dyscrasias.
Mr. Frank E. Smith, Chicago, A Doctor Enters the Insurance Field.
Dr. Robert C. Bassett, Ann Arbor, Mich., Surgical Management of Intractable Pain.
Dr. John M. Sheldon, Ann Arbor, Urticaria and Angioneurotic Edema.
Dr. Cameron Haight, Ann Arbor, Diagnosis and Management of Bronchogenic Tumors.
Dr. Henry K. Ransom, Ann Arbor, Gastric Ulcer: End Results of Treatment.
Dr. William E. Adams, Chicago, Cancer of the Esophagus.
Dr. Park J. White, St. Louis, Treatment of Certain Serious Infections in the Newborn Infant.
Dr. Thomas K. Brown, St. Louis, Management of Difficult Labor.
Dr. Robert J. Crossen, St. Louis, Cancer Potential in Involuting Organs.
Dr. Philip Lewin, Chicago, Treatment in the Early Stages of Poliomyelitis.

Topics for panel discussion Tuesday are Medical and Surgical Aspects of Blood Dyscrasias, Surgical Treatment of Hypertension, Congenital Atresia of the Esophagus, Tracheoesophageal Fistula; for Wednesday, Surgical Aspects of Carcinoma of the Colon, Abdominal Allergy and Anuria and Oliguria; Thursday, The Rh Factor and Erythroblastosis, Vaginitis in Pregnancy, The Thymus Problem, Sterile Marriages and Functional Uterine Bleeding. The Tuesday evening dinner will be addressed by Dr. Harrison H. Shoulders, Nashville, Tenn., President of the American Medical Association, on "Some Problems in the Economics of Medical Care." The Woman's Auxiliary will meet April 29 to May 1. There will also be exhibits.

Physician Honored.—Dr. John A. Waggener, Humboldt, who is completing his seventy-first year of medical practice, was honored in one of the nationwide centennial radio broadcasts February 15, conducted by the American Medical Association. Dr. Waggener came to Richardson County in November 1878. He is 94 years old.

NEW YORK

County Society Meeting.—At a meeting of the Saranac Lake Medical Society, March 5, Dr. George W. Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, and physician-in-chief, Peter Bent Brigham Hospital, Boston, spoke on "Recent Advances in Hormone Therapy."

Hospital Centennial.—Rochester General Hospital, Rochester, will mark a century of service May 7. Open house at the hospital in observance of National Hospital Day May 12, clinic day, arranged by the medical staff at the Academy of Medicine, and a banquet at the Seneca Hotel May 15 are a part of the centennial celebration.

Dr. Loper Honored.—A testimonial banquet was recently given by the executive board of the Eastern Long Island Hospital and the medical staff in honor of Dr. Arthur C. Loper of Greenport, who has practiced medicine for fifty years in that community and served many years as chief of staff of the hospital. Dr. Loper, a graduate of the College of Physicians and Surgeons in Baltimore, is the oldest member on the hospital staff.

New York City

Personal.—Dr. Bernard Samuels, New York, will give the Montgomery Lecture at the annual meeting of the Irish Ophthalmological Society, Trinity College, University of Dublin, Ireland, May 22, on sympathetic ophthalmia.

Ragweed Control.—The health department's pioneer ragweed control program last summer resulted in a reduction in atmospheric pollen for that season to the lowest count since 1937. A short comprehensive course of instruction on the control of noxious plants for the directors and sponsors of control programs in communities in the metropolitan area is being arranged by New York University.

Annual Rheumatism Association Meeting.—The annual meeting of the New York Rheumatism Association will be held at the Cornell University Medical College April 19 at 2:30 p. m. Subjects to be discussed are "The Relationship Between the Sacroiliac and Spinal Findings in Marie-Strümpell Spondylitis," "Intravenous Procaine in the Treatment of Arthritis," "Further Developments in the Etiology of the Shoulder-Hand Syndrome," "Cardiac Manifestations of Rheumatoid Arthritis" and "Neuromuscular Changes in Rheumatoid Arthritis."

Course for Institutional Food Handlers.—A course in sanitation for institutional food handlers was begun recently in New York City by Health Commissioner Israel Weinstein in connection with a campaign to clean up eating places and improve food handling methods. The course, opened on March 22, is being continued on Saturdays for fourteen weeks in the Fort Green Health Center, Brooklyn, for persons in hospitals, homes and other institutions who supervise the handling of food, under the auspices of the Catholic Charities of the Diocese of Brooklyn. The course is similar to one being given by Dr. Weinstein in Manhattan.

Two Deaths from Smallpox.—Following the disclosure April 4 that an American business man who contracted smallpox in Mexico died in the Willard Parker Hospital for Contagious Disease in March, New Yorkers are responding to the suggestion that those who have not been vaccinated since childhood do so immediately. Of three other persons who subsequently developed smallpox one died and two are recuperating at the hospital. Special clinics set up at all health centers are open until 8 p. m., and all hospital authorities have been asked by the hospital commissioner to maintain twenty-four hour service in their emergency wards for vaccinations. An intensive campaign of vaccination is already under way. Under the health laws all persons having contact with smallpox must be vaccinated or be subjected to strict surveillance by the health department for twenty-one days. The city and state health departments have joined the U. S. Public Health Service in an effort to trace contacts made by the smallpox victim en route from Mexico to New York.

Health Department Closes Five Restaurants.—Five eating places were closed, temporarily at least, March 20 by the city health commissioner. Three of the restaurants had their kitchens and all equipment sealed, while two others shut their doors for repairs before the health department arrived. Notice had previously been sent to six restaurants to clean up within forty-eight hours or be closed. Places closed were a sandwich shop at 373 Lexington Avenue, whose manager has been fined three different times since last September for lack of sanitation. The C. & H. Cafeteria, 118 Grattan Street, and the R. & B. Delicatessen Restaurant, 767 Nostrand Avenue, were sealed. Both places had previously been fined in court. The cafeteria did not have a permit from the health department as required by law, the chief inspector of food and drugs said. The two that stopped service voluntarily were a bar and grill in Williamsburg, Brooklyn, and a catering-kitchen in a church center on the West Side of Manhattan. Since the restaurant cleanup campaign began last June 6, there have been 16,963 places inspected and 2,231 summonses have been served, resulting in 2,163 fines.

OHIO

Society News.—Dr. Paul R. Cannon, University of Chicago department of pathology and president, American Society for Experimental Pathology, addressed the Mahoning Medical Society, Youngstown, in February on "Recent Advances in Protein Nutrition."

Narcotic Violation.—Dr. M. F. Vereker, 71, of Hamilton was fined $8,000 and placed on probation for two years by U. S. District Judge John H. Druffel, March 19. Dr. Vereker, indicted the previous week for selling prescriptions for narcotics to addicts, was ordered to surrender his federal narcotic license. Judge Druffel suspended the prison sentence because of Dr. Vereker's advanced age.

OREGON

Oppose Increase in Office Rental Space.—The Multnomah County Medical Society, Portland, faced with a 25 per cent increase in office space rental imposed March 5 by the management of the Medical Dental Building, met with the dental society and passed a resolution "condemning the inflationary increase in office rent and other items of overhead expense." Dr. Willard F. Hollenbeck, president, Multnomah County Medical Society, said "the medical society feels that it is in the public interest to prevent any further increase which will reflect in the cost of medical care." The management of the Medical Dental Building, it is said, has increased rents 64.5 per cent over those of 1944. When the manager and owners of the Medical Dental Building were advised of the action of the societies and invited to meet and discuss the rental increase, they failed to appear.

PENNSYLVANIA

Ophthalmology and Otolaryngology Meeting.—The annual meeting of the Pennsylvania Academy of Ophthalmology and Otolaryngology is set for April 26-27 at the Penn-Harris Hotel, Harrisburg. The group will be addressed by Drs. William L. Benedict, Rochester, Minn., on "Tumors of the Orbit"; Thomas B. McCollough, Pittsburgh, "Surgical Considerations of Supposed Nasal Allergy"; Francis H. Adler, "Problems in Diagnosis and Treatment of Chronic Simple Glaucoma"; Albert P. Seltzer, Philadelphia, "How to Do a Complete Rhinoplasty and Common Errors in Nasoplastic Surgery"; LeRoy M. Polvogt, Baltimore, "Irradiation of the Nasopharynx," and Charles F. Kutscher, Pittsburgh, "Contusions of the Eyeball."

Pittsburgh

Occupational Disease Diagnostic Clinic.—The School of Medicine of the University of Pittsburgh has established an occupational disease diagnostic clinic at the Falk Clinic. Each Saturday it is open to cases referred by physicians for study and diagnosis only, the reports being transmitted on completion of study to the referring physician. Fees for necessary laboratory work or hospital expense when deemed advisable will be charged. The clinic will provide also facilities for graduate students in industrial medicine who are enrolled in the School of Medicine.

SOUTH CAROLINA

Annual State Medical Meeting.—The South Carolina Medical Association will hold its ninety-ninth annual session May 6, 7 and 8 at Myrtle Beach under the presidency of Dr. James C. McLeod, Florence. The sessions will be addressed by:

Dr. Robert H. Felix, Washington, D. C., Development of a Mental Hygiene Program in a State.
Dr. Eugene P. Pendergrass, Philadelphia, How to Prevent Death from Cancer of the Breast.
Dr. Alfred W. Adson, Rochester, Minn., Headache.
Dr. Jessie Wright, Pittsburgh, Acute and Convalescent Stages of Poliomyelitis in Respect to Responsibility of Physical Medicine.
Dr. J. Earle Moore, Baltimore, Treatment of Syphilis.

A new feature will be the round table discussion on Thursday morning. Doctors will be allowed six minutes each to present what's new in allergy, dermatology, pediatrics, cardiology, chemotherapy, gastroenterology, obstetrics and gynecology, surgery, orthopedics and otolaryngology. Following this, questions from the audience will be answered. At the banquet Wednesday evening at 8 o'clock Dr. Pendergrass will speak on "The Atomic Bomb from Personal Observation at Bikini," showing moving pictures.

Richland County Tuberculosis Program.—An x-ray survey and health education program in Richland County has been announced by Dr. Edward P. White, Columbia, director, county health department. Every school child from the eighth through the twelfth grade and a large portion of the adult population will be given an opportunity to have chest x-ray pictures made. A follow-up of all cases considered positive will be made by a worker from the Richland County Tuberculosis Association and by staff nurses of the county health department.

TENNESSEE

Personal.—Dr. Thomas Lee Gore has been appointed superintendent of the Davidson County Hospital, Nashville, to succeed Dr. Ralph C. Eades, resigned. Dr. Gore, a graduate of the University of Pennsylvania School of Medicine, Philadelphia, served in France during the first world war and was in the Army Medical Corps until 1939, when he retired and went into business in Texas.

Annual State Medical Meeting.—The Tennessee State Medical Association held its one hundred and twelfth annual meeting in Memphis April 8-10 under the presidency of Dr. Charles M. Hamilton, Nashville. Among the guest speakers were:

Dr. Abraham Levinson, Chicago, Diagnosis and Treatment of Meningitis.
Dr. George F. Lull, Chicago, Secretary and General Manager, American Medical Association.
Dr. Joseph G. Molner, Detroit, Epidemiology and Recent Developments in Poliomyelitis.
Col. William C. Porter, M. C., Houston, Texas, Neuropsychiatry for the General Practitioner.
Dr. Ursus V. Portmann, Cleveland, Role of Surgery and Radiation Therapy for Cancer of Breast.
Frank E. Smith, Ph.D., Director, Associated Medical Care Plans, Chicago, A Doctor Enters the Insurance Field.
Dr. Harrison H. Shoulders, Nashville, President, American Medical Association, Some Problems in the Field of Medical Economics.
Dr. Dudley C. Smith, Charlottesville, Va., Management of Early Syphilis.
Dr. Fletcher D. Woodward, Charlottesville, Va., Recurrent Nerve Paralysis of the Larynx.

TEXAS

Nontechnical Educational Program.—The Dallas County Medical Society initiated a new educational program for membership applicants with the purpose to prepare aspiring doctors for their nontechnical responsibilities to patients, the public and the profession. A series of three monthly lectures are to be given on the first Tuesday of each month at 7:45 p. m. in Baylor University Hospital Library, Dallas. The first lecture is on medical organization, the second on public relations and ethics, and the third on the legal aspects of medicine. The lectures are sponsored by the society's new preceptorship committee, of which Dr. Curtice Rosser is chairman. The Texas State Medical Association executive council last September recommended the establishment of orientation schools for new doctors in every community. Dallas is reported to be the first in Texas to establish such a school.

Grants to University Medical Branch.—Five grants for research have been made to the University of Texas Medical Branch, Galveston, as follows: Dr. James B. Nail and alumni associates of Wichita Falls have made an initial grant of $500 for the establishment of a research fund for the study of deafness. It is the intention of the alumni in the Wichita Falls area to maintain this fund by annual grants. J. B. Roerig and Company, Chicago, have granted $2,500 to the Tissue Culture Laboratory for research on factors involved in cellular growth. The National Foundation for Infantile Paralysis has granted $11,675 to support a study to develop a practical serologic test for the diagnosis of poliomyelitis. The Smith, Kline and French

Laboratories, Philadelphia, have made a two year grant of $6,000 for the support of pharmacologic studies of new compounds. Mr. Meyer and Mr. Jerome Epstein, San Antonio, have given a grant of $5,000 for the purpose of establishing the Leib Epstein Medical Student Loan Fund.

WISCONSIN

Memorial Fund.—Friends of Dr. William J. Bleckwenn, professor of neuropsychiatry, University of Wisconsin Medical School, Madison, Mrs. Bleckwenn and classmates have established a memorial fund for William J. Bleckwenn Jr., who died suddenly at the University of Wisconsin, where he was president of the third year class in the medical school. Contributions to the William J. Bleckwenn Jr. Memorial Fund may be sent to Dr. William S. Middleton, Dean of the Medical School, University of Wisconsin, 418 North Randall Avenue, Madison 6.

Dr. Waters Honored.—Dr. Ralph M. Waters, professor of anesthesia at the University of Wisconsin Medical School, Madison, and director of the department of anesthesia at the State of Wisconsin General Hospital, Madison, was awarded the Order of the Vasa from the king of Sweden March 17. The award was presented by Gösta Oldenburg, Swedish consul-general in Chicago, in recognition of the physician's wartime work in training Swedish doctors in anesthesia. The Swedish government has sent four physicians to the State of Wisconsin General Hospital for training under Dr. Waters. The Order of Vasa has been conferred since 1772 for service in science, literature and the arts.

State Board Appointments.—Drs. Forrester Raine, Milwaukee, and Samuel L. Henke, Eau Claire, have been appointed to the state board of health. Dr. Raine, a graduate of Boston University School of Medicine, was in practice in Milwaukee before entering military service as chief of surgical service at Camp Grant and later as surgical consultant in the Central Pacific area. Dr. Henke, who before his appointment practiced dermatology and syphilology and was a staff member of Luther and Sacred Heart hospitals, Eau Claire, is a graduate of the University of Wisconsin Medical School. In 1943 he became an officer in the Naval Medical Reserve Corps, serving at the Farragut, Idaho, naval base and in Hawaii.

PUERTO RICO

International Health Congress.—Puerto Rico was represented at two international health conferences held in Caracas, Venezuela, recently in the person of Dr. Juan A. Pons, San Juan, new commissioner of health in the insular government. Dr. Pons was a member of the U. S. delegation to the twelfth Pan American Sanitary Conference and second Pan American Sanitary Education Conference when those congresses convened.

Central Laboratory at Rio Piedras.—A central laboratory to serve all agencies of the Puerto Rican government is to be built at Rio Piedras, home of the University of Puerto Rico, with plans calling for construction early in 1948. The laboratory will be operated by the Puerto Rico Department of Health, but its facilities will enable it to conduct research on behalf of government agencies with widely diversified functions, according to officials of the department of health in San Juan.

Social Work Convention Held in San Juan.—Under the auspices of the Association of Social Workers of Puerto Rico, a convention was held at Rio Piedras, March 21-23. The causes and cure of delinquency were the chief topics of discussion. Other individuals and organizations interested in delinquency problems in Puerto Rico participated in the discussions. Dr. Angel D. Marchand, San Juan, assistant commissioner of health of Puerto Rico, was elected president of the association for 1947.

Recommend Social Security.—Puerto Rico has adopted local legislation and procedures which would facilitate extension of the Social Security Laws of the United States to this territory, and the U. S. Federal Security Agency has recommended to Congress that certain titles of the Federal Security Law be extended to persons in Puerto Rico who now lack the protection afforded by this law. Among the beneficiaries of this action would be the blind, the aged and dependent children.

Survey of Medical History.—Dr. Manuel Quevedo-Baez, San Juan, Puerto Rican physician and writer, and other members of the medical association of this island have cooperated in the publication of a comprehensive survey of medicine and surgery in Puerto Rico. This publication is in Spanish and covers the first volume of a series tracing medical progress on he island.

GENERAL

Science Editor Dies.—Willard L. Valentine, Ph.D., editor of *Science* magazine and chairman of the Department of Psychology at Northwestern University from 1940 to 1945; died at his home in Alexandria, Va., April 5, aged 42.

Student Loan Fund in Gynecology.—The Woman's Auxiliary of the Southern Medical Association has established the Jane Todd Crawford Student Loan Fund in gynecology for young Southern physicians. The student must be not over 32, must be of good character and must show evidence of good scholarship. The loan is to be returned in small instalments after completion of study. Inquiries may be addressed to Mrs. J. Ullman Reaves, 1862 Government Street, Mobile 18, Ala.

Symposium on Heredity.—The International and Spanish Speaking Association of Physicians, Dentists and Pharmacists held a symposium on Heredity in Genetic Diseases March 31 in New York. Dr. Bernhard Zondek, Jerusalem, Palestine; Clara J. Lynch, Ph.D., Rockefeller Institute, New York; Dr. Otto Marburg, Vienna University; Dr. George W. Henry, Cornell University Medical College, New York; Myron Gordon, Ph.D., New York; Dr. A. J. Blumgarten, chief endocrinologist, Lenox Hill Hospital, New York; G. Lawton, New York, and Dr. Hyman Chartock, New York, participated.

Meeting of Council of New England Medical Societies.—The second annual meeting of the Council of the New England State Medical Societies was held at the Harvard Club, Boston, April 16. Following the business meeting the group was addressed by Drs. Norman H. Gardner, East Hampton, Conn., on "State Planning for Rural Medical Services"; Reginald F. DeWitt and Lyall H. Middleton, Plymouth, N. H., "Group Practice in the Small Community," and Mr. Ambrose B. Kelly, associate general counsel of the Association of Factory Mutual Fire Insurance Companies, "Approaches to the National Health Question."

Educational Program on Mental Health.—An expanded program of public education on the problems and needs of mental patients will be undertaken by the National Mental Health Foundation through grants of $25,000 each from the Carnegie Corporation of New York and the Rockefeller Foundation. Additional grants of $25,000 each have been promised in 1948 from the Carnegie and Rockefeller funds, provided the National Mental Health Foundation can raise $122,000 through popular subscription. The foundation publishes pamphlets and training material for mental hospital personnel and produces radio programs designed to create a wider understanding of mental health problems.

Fellowships in Ophthalmology.—The Heed Ophthalmology Foundation for training eye surgeons after they have finished residencies has recently been established by Mr. and Mrs. Thomas Heed, Evanston, Ill., by a fund sufficient to support up to three fellowships each amounting to $2,500 to $3,000. They are available to citizens of the United States. A board of five ophthalmologists representing medical schools throughout the country will handle the fellowships. Application blanks and additional information may be obtained from the secretary of the board of directors, Dr. M. Hayward Post, 520 Metropolitan Building, 508 North Grand Boulevard, St. Louis 3.

Fraudulent Salesman.—A man calling himself E. G. King recently came to the office of a physician in Malden, Mo., as a salesman of a portable obstetrics table. A special discount for cash brought the cost to $70, which the physician paid by check. King claimed to be representing the Wonder Stretcher Bed Company of Mankato, Minn. After several weeks the table had not arrived and the physician wrote the company. Later he received an unsigned note saying that no such company existed. This person was 5 feet 5 inches tall, weighed 150 pounds and had light brown hair and regular features. The victim believes that the man had visited numerous other physicians in Missouri.

Society for Study of Arthritis.—The American Anti-Arthritis Association, incorporated in California last September, maintains offices in the Los Angeles County Medical Building, 1925 Wilshire Boulevard, Los Angeles. Its purposes are to unite scientific men and women in a broad program of education for the control of arthritis; the development of a more complete understanding of the disease and new technics of prevention and therapy; to promote and engage in research in arthritis and related fields; to operate with other agencies in carrying on its purposes, and to secure funds for carrying out its projects. Drs. Bernard L. Wyatt, Los Angeles, is president; John V. Barrow, Los Angeles, vice president, and Robert T. Pottenger, Pasadena, Calif., secretary-treasurer.

International Congress of Military Medicine.—The eleventh International Congress of Military Medicine and Pharmacy is scheduled to be held in Berne, Switzerland, June 2-7, for the first time since 1939. This organization was founded soon after World War I by a group of consulting surgeons with the Allied armies. Distinguished officers of various countries have served as president, the present incumbent being Major Gen. Charles R. Reynolds, retired, former Surgeon General of the U. S. Army. The International Committee, which activates the organization between sessions, has submitted the following questions for study and report at the meeting in June: 1. Methods of reviving the wounded (reporting countries Great Britain, France and Yugoslavia). 2. General account of modern methods of preventing epidemic diseases in armies (reporting countries United States, Switzerland and Great Britain). 3. Modern methods of evacuating sick and wounded; indications and contraindications (reporting countries Canada, Russia and Poland). 4. Role played by military medicine in the moral and the physical development of the soldier (reporting countries Belgium, France and Switzerland). 5. Comparative study of methods and devices to determine the concentration of hydrogen ions with a view to their use in military pharmaceutical laboratories (reporting countries Switzerland, France and Brazil). The International Committee of Military Medicine and Pharmacy has been cooperating with the International Committee of the Red Cross concerning the revision of the conventions of Geneva and of The Hague. The committee has put forth recommendations on this subject which were considered at the meeting of governmental experts of the International Committee of the Red Cross in Geneva in March. The president of the International Committee of Military Medicine and Pharmacy is General Reynolds and the secretary general is Surgeon Major General J. Voncken of Liége, Belgium.

Grants for Cancer Research.—The Jane Coffin Childs Memorial Fund for Medical Research, New Haven, Conn., has announced appropriations made by its board of managers on Nov. 15, 1946 and Feb. 21, 1947, totaling $202,616,66 for support of cancer research projects and fellowships. Grants of over $10,000 were made to:

Dr. Francisco Duran-Reynals, associate professor of bacteriology, Yale University School of Medicine, New Haven, $49,500 for three years for continued study of the factor influencing carcinogenesis by chemicals.

Leonell C. Strong, Ph.D., associate professor of anatomy, Yale University School of Medicine, $41,290 for three years for continued genetic investigations of cancer.

Dr. William U. Gardner, Ph.D., professor of anatomy, Yale University School of Medicine, $16,500 for three years for continued investigations of the role of hormones in normal and abnormal growth.

Dr. John G. Kidd, professor of pathology, Cornell University Medical College, New York, $14,580 for three years for continued study of viruses and cancer.

Dr. David A. Karnofsky, fellow, $13,500, for three years to work with Dr. Cornelius P. Rhoads at Memorial Hospital and the Sloan-Kettering Institute for Cancer Research.

Dr. Rhoads, director, and his associates at Memorial Hospital and Sloan-Kettering Institute for Cancer Research, $10,000 for one year for continued chemical and metabolic studies of cancer, with special reference to steroids.

An allocation of $10,000 for one year to be used for expenses of conferences, lectures, consultants and travel of investigators receiving grants from the fund.

Allocation of UNRRA Funds.—The United Nations Relief and Rehabilitation Administration recently transferred one and a half million dollars to the World Health Organization Interim Commission for partial continuation of UNRRA's health programs in certain countries. A subcommittee of the World Health Organization Committee on Administration and Finance, under the chairmanship of Dr. C. Vandenberg of the Netherlands, met in February in Geneva to study reports from countries which have been receiving health assistance from UNRRA. Provisional allocations were made, *inter alia,* for a number of purposes, including the teaching program in China and such field activities as the continuation of the basic health program in Ethiopia and malaria and tuberculosis control programs in Greece. Allocations were made also for fellowships in eight countries and for visiting lectureships, for supplying medical literature in various countries and for contributions to the salaries of specialists stationed in the New York and Geneva offices of the World Health Organization Interim Commission. Among those attending the Geneva meeting was Dr. H. van Zile Hyde, Bethesda, Md., of the U. S. Public Health Service. The Interim Commission met in Geneva again March 31. Medical and health leaders from all parts of the world, some 100 in all, attended. Among the organizations which sent observers to the meeting were the United Nations Educational, Scientific and Cultural Organization, the Social Affairs Department of the United Nations, the Food and Agriculture Organization, the International Refugee Organization, the International Children's Emergency Fund, the International Labor Organization and the Provisional International Civil Aviation Organization. The chairman of the Interim Commission, which is composed of eighteen member states, is Dr. Andrija Stampar, former vice chairman of the Economic and Social Council of the United Nations. The director of the Interim Commission headquarters office, 350 Fifth Avenue, New York, is Dr. Frank A. Calderone.

PHILIPPINE ISLANDS

The Philippine College of Surgeons.—The first issue (July-August 1946) of the *Philippine Journal of Surgery,* official organ of the Philippine College of Surgeons, reviews the establishment of the college in 1936 by the late Professor Gregorio Singian at a meeting in the old San Juan de Dios Hospital, of which he was director for many years. The last prewar meeting of the board of regents was held Aug. 29, 1941. During the Japanese occupation the Philippine College of Surgeons suffered the loss of its fiscal assets and many of its records as part of the ravages of the war; it resumed its meetings a few months after American troops drove the Japanese out. Even during these trying years many surgeons, whose ambition it was to become members of the college, kept records of surgical operations, a requirement of applicants, some of them doing so under great hardships. The purposes of the college are the elevation of standards of medical education and practice and the promotion of surgical science and art.

CANADA

National Cancer Institute.—A National Cancer Institute to coordinate all Canadian cancer control work was launched at a two day conference in Ottawa in January. One immediate objective will be the enlistment of every physician in the preparation of careful case records. Physicians will be urged to submit to the institute every possible angle of attack to further cancer control. An interim committee was appointed to proceed in dealing with grants and research projects while the National Cancer Institute is being legally incorporated. The chairman of the committee is Dr. Allan W. Blair, Regina, Sask. Dr. John L. Little, Guelph, Ont., is serving as executive secretary, with headquarters at the Jackson Building, Ottawa.

FOREIGN

Medical Science Center in Rome.—The Italo-American Center for Medical Science has been established in Rome, Italy, for the purpose of renewing cultural exchanges between Italy and the United States interrupted by the war. The center has been authorized by the Italian foreign office. The president is the minister of education, the vice president is the president of the American Relief of Italy and among the directors are the rector of the University of Rome, three professors and a representative of the foreign office. The address of the center is Via Torino, 122, Rome, Italy.

CORRECTION

Rickettsialpox.—In the article by this title in The Journal, March 29, page 905, second column, line 20, the word "lymphocytes" should have read "lymph vessels."

Marriages

Allison Mondoville Alderman Jr., Wilmington, N. C., to Miss Willie Ruth Edwards of Winston-Salem Dec. 16, 1946.

Carvel M. James, Beverly Hills, Calif., to Miss Norma Talmadge in Las Vegas, Nev., Dec. 4, 1946.

Aloysius Patrick Harney, New Bedford, Mass., to Miss Nina Louise Parker of Boston Dec. 28, 1946.

Andy Hall Jr., St. Louis, to Mrs. Martha Eileen Sanderson of St. Paul in November 1946.

Abraham A. Goetz, Baltimore, to Miss Natalie Wolf of Yonkers, N. Y., March 9.

Daniel K. Adler to Miss Rosamond Small, both of Syracuse, N. Y., February 16.

Martin Ackerman to Miss Lucille Diamond, both of New York, March 16.

Robert E. Bodwin to Miss Leona Corthier, both of Chicago, recently.

Deaths

George P. Muller ⊕ Philadelphia; born in Philadelphia, June 29, 1877; University of Pennsylvania Department of Medicine, Philadelphia, 1899; Grace Revere Osler professor of surgery at Jefferson Medical College of Philadelphia from 1939 to 1946, when he became professor emeritus of surgery; formerly professor of clinical surgery at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, and his alma mater; member of the founders group of the American Board of Surgery; fellow, member of the board of regents and past president of the American College of Surgeons; past president of the Philadelphia County Medical Society, Philadelphia Academy of Surgery, College of Physicians of Philadelphia and the American Association for Thoracic Surgery; member of the American Surgical Association and the Society of Clinical Surgery; served during World War I; served on the staffs of the White Haven (Pa.) Sanatorium, Rush Hospital for Consumption and Allied Diseases, Lankenau, Jefferson and Misericordia hospitals; received honorary degrees from the Villanova (Pa.) College in 1916 and the Muhlenberg College in Allentown, Pa., in 1937; on the editorial board of *Annals of Surgery;* died in Margate, N. J., February 18, aged 69, of cerebral thrombosis.

Earl Calvin Padgett ⊕ Kansas City, Mo.; born in Greenleaf, Kan., July 8, 1893; Washington University School of Medicine, St. Louis, 1918; professor of clinical surgery at the University of Kansas School of Medicine; professor of oral surgery and maxillofacial surgery at the Kansas City Western Dental College; diplomate of the National Board of Medical Examiners; member of the founders group of the American Board of Surgery; specialist certified by the American Board of Plastic Surgery; member of the American Surgical Association, Western Surgical Association and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served in France during World War I; on the staffs of the Children's Mercy Hospital, Kansas City General Hospital, Kansas University Hospitals, Menorah Hospital and Providence Hospital, all of Kansas City, Kan., St. Mary's and St. Luke's hospitals; died Dec. 2, 1946, aged 53, of lobar pneumonia.

William Barnett Owen ⊕ Louisville, Ky.; born in Hart County, Ky., March 12, 1880; Kentucky University Medical Department, Louisville, 1903; clinical professor and head of the department of orthopedic surgery at the University of Louisville School of Medicine; chairman, Section on Orthopedic Surgery, American Medical Association, 1932-1933; specialist certified by the American Board of Orthopaedic Surgery; past president of the Clinical Orthopedic Society; member of the American Orthopaedic Association, Southern Surgical Association, Southeastern Surgical Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons, formerly affiliated with the U. S. Public Health Service; chairman of the staff of Kosair Crippled Children's Hospital; on the staffs of the Children's, St. Joseph and Kentucky Baptist hospitals and Norton Infirmary; died February 23, aged 66, of carcinoma of the stomach.

Victor Robinson, New York; born in Russia on Aug 16, 1886; Chicago College of Medicine and Surgery, 1917; also a graduate in pharmacy; professor of the history of medicine at the Temple University School of Medicine, Philadelphia; served as president of the New York Society for Medical History; founding member of the History of Science Society; an official delegate to the International Congress of the History of American Medicine, Leyden-Amsterdam, Netherlands, in 1927; a council member of the American Association of the History of Medicine from 1939 to 1941; fellow of the New York Academy of Medicine and chairman of its section on history and cultural medicine, 1944-1945; member of the Institute of Aeronautical Sciences; editor of the Pagel-Sudhoff Handbook of the History of Medicine and author of "Pathfinders in Medicine" and numerous other works; died January 8, aged 60, of coronary thrombosis.

Franklin Fayette Lane ⊕ Captain (MC), U. S. Navy, retired, Philadelphia; born in Elm, N. J., on Aug. 21, 1888; University of Pennsylvania School of Medicine, Philadelphia, 1915; member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology and American Board of Otolaryngology; fellow of the American College of Surgeons; entered the medical corps of the U. S. Navy as a lieutenant (jg) in 1917; placed on the retired list January 1 after having served actively for about twenty-nine and one-half years; served as a member of the Naval Retiring Board, Navy Department in Washington, D. C.; died January 29, aged 58, of aneurysm of the aorta.

Lee Welsey Pollock ⊕ Rochester, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1912; entered the Mayo Clinic as a member of the clinical staff in November 1914, appointed associate in medicine, and in April 1925 appointed head of a section in medicine; assistant professor of medicine at the Mayo Foundation; during World War I was a first lieutenant in the medical corps of the U. S. Army and served on the board of examiners for tuberculosis in various army camps; affiliated with St. Mary's Hospital, Colonial Hospital, Worrall Hospital and the Kahler Hospital, where he died February 2, aged 58, of left hemiplegia and pulmonary embolism.

Howard Gustav Schleiter ⊕ Pittsburgn; University of Pennsylvania Department of Medicine, Philadelphia, 1905; associate professor emeritus of medicine at the University of Pittsburgh School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Clinical and Climatological Association; served in France during World War I; consultant at the Pittsburgh Diagnostic Center; on the staffs of the St. Francis Hospital and the Allegheny General Hospital, where he died February 5, aged 66, of hemorrhage due to peptic ulcer.

Charles Henry Hare ⊕ Boston; Harvard Medical School, Boston, 1889; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; member of the Boston Society for Medical Improvement and the Boston Obstetrical Society; at one time instructor in gynecology at Harvard Medical School, Courses for Graduates, and on the faculty and dean of the Boston Polyclinic; served on the staffs of the City Hospital in Quincy, Mass., Boston Dispensary, Carney Hospital and St. Elizabeth's Hospital; died January 21, aged 84.

Joseph Albert Abercrombie ⊕ Richlands, Va.; Johns Hopkins University School of Medicine, Baltimore, 1930; served an internship and residency at Johns Hopkins Hospital in Baltimore; member of the state board of health; consultant on the Selective Service Board during World War II; on the staffs of the Grundy (Va.) Hospital and Mattie Williams Hospital; died January 12, aged 40, of cerebral hemorrhage.

Harold Edwin Andrews, Buffalo; Boston University School of Medicine, 1925; member of the American Medical Association; served during World War II; died January 21, aged 48, of coronary thrombosis.

Edna Blanche Averill, Springfield, Mass.; Boston University School of Medicine, 1910; died Dec. 25, 1946, aged 76, of bronchopneumonia.

William Thomas Baker ⊕ Louisville, Ky.; Hospital College of Medicine, Louisville, 1892; died in the Jackson Memorial Hospital, Miami, Fla., January 28, aged 76, of injuries received when struck by an automobile.

Cecil Ernest Barnett ⊕ Kirkwood, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1917; died in St. Mary's Hospital, Clayton, Dec. 23, 1946, aged 54, of coronary thrombosis.

Frederick James Bentley ⊕ Seattle; Rush Medical College, Chicago, 1901; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; member of the staffs of the Children's Orthopedic and King County hospitals; died January 1, aged 71, of coronary embolism.

Francis Stephen Caldicott, Lowell, Mass.; Tufts College Medical School, Boston, 1913; member of the American Medical Association; served during World War I; designated examiner for the U. S. Veterans Administration; on the courtesy staffs of St. Joseph Hospital, St. John's Hospital and the Lowell General Hospital, where he died January 17, aged 57, of coronary thrombosis.

Benjamin Franklin Campbell ⊕ Burlington, Iowa; College of Physicians and Surgeons, Keokuk, 1897; Northwestern University Medical School, Chicago, 1904; died Dec. 31, 1946, aged 72, of hypertensive cardiovascular disease.

George Ralph Christie, Long Prairie, Minn.; Rush Medical College, Chicago, 1882; member of the American Medical Association; formerly mayor and president of the school board; died in the Asbury Hospital, Minneapolis, January 20, aged 89, of pneumonia following an operation.

Thomas Francis Coughlin Jr., Hoboken, N. J.; University of Tennessee College of Medicine, Memphis, 1917; served during World War I; on the staffs of the North Hudson Hospital, Weehawken and St. Mary's Hospital, where he died January 5, aged 63, of heart disease.

Frank Leander Crikelair, Green Bay, Wis.; Milwaukee Medical College, 1908; member of the American Medical Association; past president of the Brown-Kewaunee-Door Counties Medical Society; served during World War I; died January 13, aged 62, of coronary occlusion.

Matthias James Crowe, St. Louis; St. Louis University School of Medicine, 1927; served on the staff of the Christian Hospital, where he died January 17, aged 42, of cirrhosis of the liver and splenomegaly.

William Elton Day, Clarksville, Iowa; State University of Iowa College of Medicine, Iowa City, 1902; member of the American Medical Association; died January 9, aged 72, of coronary thrombosis.

Charles Edward Fisher, Lyons, Kan.; Northwestern University Medical School, Chicago, 1903; served as secretary of the Rice County Medical Society; affiliated with the Lyons Hospital, where he died January 19, aged 69, of heart disease.

William Dabney Gholston, Danielsville, Ga.; University of Georgia Medical Department, Augusta, 1900; member of the American Medical Association; secretary of the Tenth District Medical Society; past president of the Clarke-Madison-Oconee Counties Medical Society; formerly member of the state general assembly; died in Athens Dec. 18, 1946, aged 76, of cerebral hemorrhage.

George Henry Goode, Pittsburgh; Miami Medical College, Cincinnati, 1883; died Dec. 22, 1946, aged 85, of arteriosclerotic heart disease.

Herbert Lewis Johnson, Hadley, Mass.; Medical School of Maine, Portland, 1884; member of the American Medical Association; died Dec. 22, 1946, aged 87, of uremia.

Isaac William Jones ⊕ Los Angeles; Kentucky School of Medicine, Louisville, 1904; died Dec. 23, 1946, aged 70, of coronary arteriosclerosis.

Edward James Kendall, Detroit; Hahnemann Medical College and Hospital of Philadelphia, 1895; for many years on the staff of the Grace Hospital; formerly member of the city board of health; died January 10, aged 86, of carcinoma of the rectum.

Herman Kessler, Hatboro, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1939; member of the American Medical Association; received a military award for his work in the Selective Service System; died in the Jefferson Hospital, Philadelphia, January 10, aged 37, of carcinomatosis.

Herschel W. Lancaster ⊕ Nevada, Mo.; Beaumont Hospital Medical College, St. Louis, 1892; an Affiliate Fellow of the American Medical Association; on the staff of the Nevada Hospital; died January 17, aged 84, of chronic valvular heart disease.

Robert Edwin McBride ⊕ Las Cruces, N. M.; Medical Department of Tulane University of Louisiana, New Orleans, 1896; fellow of the American College of Physicians; at one time secretary of the New Mexico Medical Society and the Dona Ana County Medical Society; served as superintendent of the county school system, member of the school board, county health officer and local surgeon for the Atchison, Topeka and Santa Fe Railroad; director of the Bowman Bank; died January 17, aged 73, of cerebral hemorrhage.

William Smith McFarland, Zanesville, Ohio; College of Physicians and Surgeons, Baltimore, 1886; died recently aged 83.

Walter Wyatt McKay ⊕ Warren, Ohio; Western Reserve University Medical Department, Cleveland, 1910; fellow of the American College of Surgeons; past president of the Trumbull County Medical Society; member and past president of the staff of the Warren City Hospital; died recently, aged 65, of coronary thrombosis.

Olin Burr Martin, Williamsburg, Ohio; Ohio Medical University, Columbus, 1903; died recently in the Christ Hospital, Cincinnati, aged 67, of thrombosis.

Frank Leslie Matousek, Cicero, Ill.; Rush Medical College, Chicago, 1938; member of the American Medical Association; interned at the Chicago Memorial Hospital; served as a captain in the medical corps, Army of the United States, during World War II; died in Marshfield, Wis., Sept. 15, 1946, aged 42, of Addison's disease.

Charles Everett Nicholson, Pittston, Pa.; Medico-Chirurgical College of Philadelphia, 1915; member of the American Medical Association; served in France during World War I; on the staff of the Pittston Hospital; died January 19, aged 59, of coronary thrombosis.

William Ernest Oglesbee, Harveysburg, Ohio; Medical of Ohio, Cincinnati, 1890; died recently, aged 79.

Byron Palmer, Santa Monica, Calif.; Starling Medical Colllege, Columbus, 1900; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty, died recently, aged 71, of coronary thrombosis.

John Samuel Phelps, Lynn, Mass.; Harvard Medical School, Boston, 1893; member of the American Medical Association; formerly medical director of the Columbian National Life Insurance Company; died Dec. 3, 1946, aged 80, of coronary occlusion.

Edward Reuben Prigger ⊕ Penns Grove, N. J.; Jefferson Medical College of Philadelphia, 1910; died Dec. 27, 1946, aged 57, of coronary thrombosis.

Edwin Almiron Riley ⊕ Park Falls, Wis.; Rush Medical College, Chicago, 1897; served during World War I; affiliated with the Park Falls Hospital; died January 21, aged 75, of carcinoma.

Amos Sherbon, Central City, Iowa; State University of Iowa College of Medicine, Iowa City, 1910; died in St. Luke's Hospital, Cedar Rapids, Dec. 27, 1946, aged 73, of thrombosis of the common iliac artery.

Frederick Joshua Simmonds ⊕ Boston; Middlesex College of Medicine and Surgery, Cambridge, 1917; died in the U. S. Naval Hospital, Chelsea, Dec. 6, 1946, aged 68, of cerebral thrombosis.

Allen Walters Sivyer, Milwaukee; University of Pennsylvania School of Medicine, Philadelphia, 1915; life member of the Milwaukee Academy of Medicine; for many years assistant medical director of the North Western Mutual Life Insurance Company; served in France during World War I; died in the Columbia Hospital Dec. 10, 1946, aged 55, of coronary thrombosis, old hemiplegia and arterial hypertension.

Eugene Albert Smith, Wauwatosa, Wis.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; served as assistant clinical professor of surgery at the Marquette University School of Medicine, Milwaukee; veteran of the Spanish-American War and World War I; at one time physician at the state prison in Waupun; retired superintendent and clinical director of the Milwaukee County Dispensary-Emergency Unit; died Dec. 1, 1946, aged 76, of leukemia and heart disease.

Marshall Bruce Stewart, Dormansville, N. Y.; Temple University School of Medicine, Philadelphia, 1932; member of the American Medical Association and the Michigan State Medical Society; began active duty as a captain, medical corps, Army of the United States, in 1941; service terminated with rank of major in September 1945; died Dec. 3, 1945, aged 53, of cancer of the pancreas.

George Lyman Taylor, Warwick, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; died in Northfield Dec. 4, 1946, aged 85, of cerebral hemorrhage.

William Flint Tidwell, Pittsburg, Ill.; St. Louis College of Physicians and Surgeons, 1901; died January 17, aged 67.

John Metcalf Trible ⊕ Houston, Texas; St. Louis University School of Medicine, 1907; professor of urology and chairman of the department at Baylor University College of Medicine; past president of the Harris County Medical Society; served in France during World War I and later with the Army of Occupation; served at one time as chief of staff at Memorial Hospital, and was on the staffs of the Jefferson Davis, City-County and Methodists hospitals and St. Joseph's Hospital, where he died January 20, aged 62, of coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Donald Richard McKay, Fargo, N. D.; Northwestern University Medical School, Chicago, 1941; served an internship at the Ancker Hospital in St. Paul and a residency at the St. John's Hospital in Fargo; began active duty as a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on Nov. 9, 1942; promoted to lieutenant; killed in an explosion on the U. S. S. *Mount Hood* at Manus Island in the South Pacific Nov. 10, 1944, aged 30.

Thomas Gervase Walsh ⊕ Chicago; Rush Medical College, Chicago, 1923; served as associate professor of medicine at the University of Illinois College of Medicine; formerly on the faculty of his alma mater; interned at the Cook County and Mercy hospitals; a captain in the medical corps of the U. S. Naval Reserve and affiliated with the Naval Hospital at San Diego during World War II; served for two years in the Pacific theater; died Nov. 4, 1946 while on special leave, aged 50, of heart disease.

The Results of Prefrontal Leukotomy

The operation of prefrontal leukotomy was introduced by Moniz of Lisbon in 1935 for the treatment of certain forms of mental disease The idea was to break the connection between the patient's thoughts and his emotions, thus relieving mental tension The frontothalamic tract, which connects the prefrontal area with the thalamus, is divided with this object It is now possible to assess the results in a large number of cases treated in this country In 1935 the Board of Control (which controls the administration of all mental institutions) started an inquiry into the results in 1,000 cases. The operative risks include death from hemorrhage (19 cases in the series) or from a complication such as bronchopneumonia (4 cases), meningitis (3 cases), cerebral abscess, respiratory failure, subdural hematoma or empyema (of each 1 case), development of epileptiform fits or other postoperative symptoms, and changes of personality. The surgeon cannot be certain of cutting the frontothalamic fibers In a case recorded by A. Meyer a schizophrenic patient did extremely well, becoming happy and unworried But when he died of cancer of the esophagus eighteen months later necropsy showed that the frontothalamic fibers had not been cut and the nucleus medialis dorsalis had not degenerated Hence it is suggested that damage anywhere in the brain may have a beneficial effect in some of the cases

Of the 1,000 cases 348 occurred in males and 652 in females For statistical purposes the cases were grouped under the diagnoses of schizophrenia, manic-depressive insanity; neurosis (*a*) obsessional, (*b*) other; postencephalitic states; mental defect; epilepsy, various Patients discharged recovered amounted to 24 8 per cent and improved to 10 5 per cent making together 35 3 per cent of the patients treated Of these 9 3 per cent relapsed Only 1 per cent were made worse by the operation; 24 7 per cent remained in the hospital unchanged Of 6 per cent who died only half did so as a result of the operation, in 19 of these hemorrhage was the cause. Fits after the operation were reported in 3 3 per cent; only in 2 1 per cent was there more than one fit. For the schizophrenic patients treated there was a discharge rate—recovered or improved—of 23 per cent, excluding those who relapsed For the manic-depressive patients the discharge rate was fifty per cent

The board concludes that prefrontal leukotomy is usually a simple operation for the patient, if not always easy for the surgeon Complications are rare, and the death rate cannot be said to be high when the seriousness of the established mental disorder is taken into account Remarkable improvement in mental behavior follows in a large percentage of patients who have had severe symptoms with poor prognosis and have failed to respond to other treatment Many are discharged from the hospital and others have become more placid and easier to nurse. The operation should be done only after each case has been carefully considered by experienced psychiatrists

Tests With Streptomycin

The Ministry of Health reports that clinical tests are being carried out with the American drug streptomycin by the Medical Research Council. Until they are completed it is not possible to assess the value claimed for the drug and to determine the best methods of use The latest American opinion indicates that its value in tuberculosis is still unproved The minister of health does not wish to hamper individual doctors and hospitals in their endeavors to obtain any new drugs which they consider may benefit their patients, but it must be emphasized that streptomycin is potentially dangerous and may have serious ill effects, including permanent giddiness and deafness The minister states that not enough is known about the drug at present to justify action by the government to make it more freely available For instance in a very small number of patients with tuberculous meningitis whose life has been prolonged by this treatment there has been nearly always permanent serious mental derangement, blindness or deafness. Steps are being taken to accelerate production in this country so that supplies may be available if the clinical trials are favorable.

Research in Geriatrics

The trustees of the Nuffield Foundation have offered the University of Cambridge the sum of $80,000, with a possible further $72,000, for research under Professor F. C. Bartlett at the psychologic laboratory into the causes and results of aging, with particular reference to adults and to the characteristics and changes of human function associated with different age groups It is proposed that the gift shall include $8,000 for capital outlay, with a further $2,400 a year for three years and a possible renewal for another three years.

Doctors and Old Age Insurance

The extension, starting with old age insurance, as from the 1st of January of the National Security law to all French citizens and especially to isolated workers and to members of the liberal professions, has aroused reactions among those concerned The National Council of the Order of Doctors has taken the initiative of convening qualified representatives of all the liberal professions (pharmacists, dentists, midwives, veterinarians, barristers, chartered accountants) in order to reach a similarity of action on this subject After the delegates of these orders got in touch with the Social Security Fund, the director of this organization made the statement that the Social Security law must be extended obligatorily to every Frenchman, and no exception for the liberal professions is possible, the import of the law being the national solidarity On the other hand, he admits professional solidarity and sees no inconvenience in the creation of supplementary autonomous funds to cover the risks of illness, old age and death The social security organization is considering the abolition in the near future of the limitation of revenue for obtaining the allocation to aged workers, and this would allow everybody to benefit of the old age pension The president of the National Order of Doctors has already had interviews with the various Medical Mutual Help Societies with a view to promoting a federation of those in order to coordinate their activities.

Miscellaneous

The United States government has granted a certain allocation of streptomycin to the French Ministry for Public Health, which has appointed as treatment centers for Paris the Claude Bernard Hospital, the Hospital for Sick Children and the Trousseau Hospital and for Algiers the Hospital for Infectious Diseases

Among those who have been elected foreign associates to the Academy of Surgery are Surgeon General Paul R. Hawley; Dr E D. Churchill, Boston; Dr. E A. Graham, St. Louis; Dr. Alfred Blalock, Baltimore; Sir Alfred Webb-Johnson, London; H W. Bell Cairns, Oxford; J. M. Graham, Edinburgh; A. E. Porrit, London; Walter Rowley Bristow, London; Burdenko, Russia, posthumously; J. J. Djanneldze, Leningrad.

The twenty-sixth French Congress of Medicine will meet in Paris on the 16th, 17th and 18th of October.

MOSCOW

March 4, 1947.

The Conservation of Lenin's Body

In 1934 the Soviet government decided to preserve the body of Lenin, leader of the Great October Socialistic Revolution. It was decided to conserve it as it was on the day of Lenin's death on Jan. 21, 1924 and to erect a mausoleum. During the twenty-three years that have passed, about 20,000,000 people from all over the world have visited the mausoleum, now a national shrine of the Soviet Union. In 1924 science did not possess perfect methods for durable conservation, methods making possible a long conservation of the body with features unchanged so that they may be observed for centuries. The Egyptian method of embalming results in desiccation of tissues, with a shrinking of internal organs and shriveling of the skin. Thus the resemblance is completely lost. In the early middle ages there were attempts to embalm—for instance King Henry I of England (1135 A. D.) and Pope Alexander Fifth (1410 A. D.). These attempts failed because of numerous changes observed in a short time. The method of injecting of fluids into blood vessels widely used at present in the United States does not guarantee long preservation without change of external features. Aiming to obtain a durable conservation without alternation of features, the late professor of anatomy V. Vorobjev and professor of biochemistry B. Zbarsky used with excellent results the latest scientific discoveries. They were verified many times by special committees. Eminent scientists, members of those committees, Professors Abrikosov (anatomist), Orbelli (physiologist), Burdenko (surgeon) and others stated in their last scientific report that the problem of preserving Lenin's body for a long time was solved with great success. It is believed that the preservation will remain almost indefinitely. A special research laboratory is set up at the mausoleum, where Professor Boris E. Zbarsky continues his work with many collaborators. At present there is no doubt that future generations will be able to see Lenin in his mausoleum appearing as not dead but asleep.

Cytral

Vitamin A has a clearly determined antihistamine effect. Cytral is a "fragment" of vitamin A. It neutralizes the action of 1 Gm. of 1:50,000 histamine solution, while vitamin A and β-ionin neutralize it in a 1:15,000 solution. Benadryl is a synthetic antihistamine of an anesthetic type. It has a cumulative action which is absent in cytral. Cytral is a yellow oily liquid obtained from the seeds of coriandrum, a plant from the umbrella family. It was tested in the clinic of Professor Mikhaïl S. Vovsi (Moscow) and in other hospitals for hypertension as an aqueous or aqueous-colloidal solution. The dose varied between 12 and 25 mg. daily. Usually in ten to fourteen days the headache passed, high blood pressure fell and weakness diminished. In the incipient forms of pregnancy toxicoses vomiting and nausea disappeared. Cytral is most effective in keratitis, conjunctivitis and especially in glaucoma. Its positive action was verified by Professor Evgenia A. Kaminskaya-Pavlova of the Moscow Central Institute of Ophthalmology in the name of Helmholtz. Eye drops with cytral diminished pain and intraocular tension.

Soviet Physicians in India

The delegation of Soviet scientists at the thirty-fourth Indian Scientific Congress at Delhi recently returned to Moscow. Soviet medicine was represented by a parasitologist, Academician Evgeni N. Pavlovsky, head of the Tajik branch of the Academy of Sciences of the Soviet Union and by Professor Sultan Umarov, rector of the Central Asia University in Tashkent. They read reports on natural niduses of insect transmitted diseases. After the congress ten foreign scientists, including Academician Pavlovsky, were honored with a degree of doctor *honoris causa*, and they were received by Pandit Nehru, president of the Indian provisory government.

The Death of Professor Herzen

After a serious illness the surgeon Professor Piotr A. Herzen died in Moscow January 2. He was the grandson of the writer Alexander I. Herzen. He graduated at the Basel and Lausanne universities (Switzerland). In czarist Russia, foreign medical diplomas were not valid, and in order to get permission to work in his native Russia P. A. Herzen had to graduate a second time in 1898. Professor Herzen became president of the Moscow Surgical Society and in 1929 was president of the twenty-first All-Union Congress of Surgeons. Professor Herzen published about a hundred scientific works. He is widely known through all the medical world. He proposed fifteen new operative methods and performed himself about 20,000 operations. He was director of the Moscow Neoplasm Treatment Institute. Many of his former pupils are now occupying surgical chairs in the universities of our country. He was decorated by the government with several orders.

ITALY

(From Our Regular Correspondent)

March 17, 1947.

National Neurologic Convention

The first National Neurologic Congress was recently held in Genoa on the initiative of Professor De Lisi, director of the Neurologic Clinic of the University of Genoa. The purpose of the meeting was to give a new life to the Italian Neurologic Association, to define and to prepare the means for the teaching and hospital interests of this specialty, to establish scientific contacts among adepts of this medical branch for the first time since the war and after a long period of silence of the association (inactive for practically fourteen years). Two hundred scientific communications were presented in the program of the convention. The three chief groups of problems discussed were (1) physicochemical phenomena of transmission of nervous impulse, (2) diagnosis and treatment of herniated intervertebral disk and (3) symptomatology and etiology of arachnitis. Professor Spadolini of the University of Pisa read a paper on the changes effected by the action of the chemical mediators on the visceral effectors. Professor Visintini of Turin presented a critical review of the chemical concept of the mediation of acetylcholine in the transmission of nervous excitation. Professor Delitala of the University of Bologna told of his experience with more than 300 laminectomies performed for hernia of the intervertebral disk. Among all the mechanical changes which may cause sciatalgia of surgical type, hernia of the disk may most easily be demonstrated. In performing laminectomy a projection may be observed which reminds one of the nodes of the fingers; after the incision of the posterior ligament there appears white chafed tissue. After the removal of the herniated tissue the nerve root, which appears edematous and stretched, resumes its normal position. Dr. Bonola of Bologna concluded from x-ray examinations of the spinal cord and from myeloscopy carried out as an aid to the diagnosis of the localization of the posterior hernia of intervertebral disk that such investigation may furnish important elements to demonstrate the presence and the seat of the hernia and may confirm the facts furnished by neurologic examination. Myeloscopy was carried out by means of a board which may suitably be dipped and which has been designed by the Instituto Rizzoli di Bologna. Professor Neri of Bologna illustrated the symptomatologic value of the electric exploration of the paravertebral spinal region. In 40 cases of hernia of the disk with symptoms of sciatalgia faradic stimulation revealed intense pain at the level of the disk, radiating downward with a variable extent of 4 to 8 cm. Electric exploration likewise reveals zones of tabetic and syringomyelic hyperalgesia. Professor Belloni of the University of Padua discussed the roentgenologic diagnosis of encephalic arachnitis and recommended the use of arteriography by the percutaneous route to furnish useful data for the diagnosis of encephalic tumors. Professor Lunedei of the University of Florence presented etiopathologic reports on arachnoiditis and endocraniosis, asserting that the syndrome of Morgagni or of Stewart-Morel (endocraniosis), for which recently the term metabolic craniopathy has been coined by American authors, should be combined in a single morbid group together with chronic primary arachnitis, with some types of essential hemicrania and with some forms of chronic diencephalitis; for this group the term "chronic frontobasilar phlogosis" may be used. Professor Salotti of Siena spoke about roentgenologic symptomatology of chronic meningeal phlogosis and of endocraniosis; based on the x-ray observations three phases of the disease may be distinguished: an initial phase of hypertension and congestion, a second phase with incipient, irreversible changes of the skeleton and of the meninges and a third phase of definite and progressive changes of the skeleton. Encephalography by means of air and particularly cisternography proved to offer great symptomatologic aid to the diagnosis of arachnoiditis. The attendants of the convention voted for the reconstruction of the Italian Association of Neuropathology and Biology of the Nervous System, which should also enlarge its field by caring for the teaching and the hospital and professional interests of members of the specialty.

ANKARA

(From Our Regular Correspondent)

Jan. 15, 1947.

Ninth National Turkish Medical Congress

A national medical congress has been held every two years since 1925. At the fifth congress in 1933 delegates from neighboring countries also attended. Between 1938 and 1943 there was no meeting. At all congresses two topics have predominated, medical matters and those pertaining to health and social assistance. On the agenda have been reports on malaria, trachoma, tuberculosis, syphilis, cancer, scarlet fever, rachitis, rheumatism, influenza, intestinal parasites, toxicomania, eugenics, nutrition, infant mortality, hot springs and sports. Physicians of all organizations, military and civil service, private practitioners, pharmacists, dentists and chemists may attend the meeting. The membership fee is 3 Turkish pounds. Congress publications and proceedings are free of charge. A reduction of 20 per cent on transportation and at hotels is granted members coming from other parts of the country. Every congress is accompanied with an exhibition of domestic and foreign pharmaceutical preparations and public health propaganda. After the congress the health exhibition is open to the public. At the last congress medical and surgical instruments and hospital equipment of domestic origin were on view.

Under the auspices of Ismet Inönü, president of Turkey, and with Recep Peker the prime minister as honorary president, the ninth congress was held from October 21 to 23 and was attended by almost a thousand members from all parts of the country. Two main themes were debated, avitaminosis and health problems in rural communities. After a general discussion on vitamins, (*a*) biology and sources of vitamins in Turkey and (*b*) pathology and diseases of avitaminosis in Turkey in adults, the same subject in relation to children was taken up by Prof. Dr. Ihsan Hilmi Alantar and (*c*) the importance of vitamins in regard to food preparation by Prof. Dr. Burhan Tugan. Papers on rural health problems were read by Prof. Drs. M. Erel and B. F. Ural, the former concerning himself with general and individual measures to be taken in regard to sanitary installations in rural communities and the latter with the necessity for cooperation of government and public in connection with public health problems and health education in rural communities. Almost 80 per cent of Turkey's 20 million inhabitants are living in 40 thousand villages, which shows how urgent is immediate attention. Presentation of papers on the subject gave other members the opportunity of expressing their views, which gave rise to lively discussion. Seventy-three communications on other topics were received.

On the occasion of this congress the second microbiologic and the fifth surgical convention were also held in Ankara. The tenth medical congress is to be held in 1948 and is to last four days. The president is to be the minister of health and social assistance, and the topics will be industrial hygiene, the physician in industry and diseases of the thyroid.

Increase in Specialists

When the regulations pertaining to specialists were published in 1929 general practitioners were also treating diseases that really needed the attention of a specialist. In 1929 a commission of university professors and specialists of the Ministry of Health was appointed by the same ministry to investigate the certificates of all physicians professing to be specialists, obliging those whose certificates were unsatisfactory to undergo another examination before their certificates could be endorsed. Since then the number of specialists has been increasing steadily. Of the more than 5,600 physicians, 491 are specialists in internal medicine, 357 in surgery, 203 in obstetrics and gynecology, 170 in bacteriology, 145 in biochemistry, 144 in ophthalmology, 120 in dermatology and venereal diseases, 105 in pediatrics, 101 in otolaryngology, 94 in psychiatry and nervous diseases, 91 in radiology, 63 in urology, 32 in pathology, 25 in legal medicine and 14 in physical medicine. There are only 12 physicians engaged in hygiene and preventive medicine, which is a comparatively new field in Turkey. Most of these 12 physicians have been in the United States as recipients of the Rockefeller Foundation Fellowships, undergoing a course of training in this important branch.

For years most new graduates have specialized in internal diseases, obstetrics, surgery and pediatrics, while the number of those deciding to specialize in hygiene, bacteriology and research work has greatly decreased. For this reason the Ministry of Health decided to oblige a sufficient number of students who studied at the expense of the government and who graduated with highest marks to specialize in laboratory work at the Central Institute of Hygiene in Ankara. The time spent there in pursuit of these studies will be deducted from the obligatory government service. Most physicians in obligatory government service are employed as health officers in the eastern provinces.

Physicians in the National Assembly

The National Assembly usually opens after October 29, the anniversary of the republic, and terminates in June. If need arises the assembly may be called on to meet at any time.

The seventh assembly was in session till July 1946. So far 4,862 laws have been passed during the twenty-four years. At present there are two medical men in the Council of Ministers; one is Dr. Behcet Uz, the minister of health and social assistance, the other Dr. Sadi Irmak, the minister of labor. The late Dr. Refik Saydam was prime minister from 1939 till 1942. Of the 425 members 44 are physicians, 70 lawyers, 32 economists, 66 military men, 37 business men, 50 farmers, 50 educationalists, 70 administrators, 29 pressmen, 27 financiers, 12 diplomats, 7 dentists, 5 engineers, 2 pharmacists and 2 veterinarians. Of foreign languages spoken by members of the assembly 259 know French, 73 German, 40 English, 39 Arabic, 29 Greek, 22 Persian, 12 Russian, 11 Italian, 5 Armenian, 4 Bulgarian and 1 Spanish.

Correspondence

UROLOGIC COMPLICATIONS

To the Editor:—The terms "tidal drainage" and "tidal irrigation" used in the article "Urologic Complications in Injuries of the Spinal Cord" in The Journal, February 8, are confusing. As many different designs of tidal drainage apparatus have appeared in the literature, it is not clear which apparatus was on trial or, in fact, whether or not one type of apparatus was used for "tidal drainage" and another for "tidal irrigation."

It is to be expected that hand irrigation would be more effective than the use of the apparatus, because none of the commonly used tidal drainage designs are capable of irrigating the bladder in the usual sense of the term. These devices merely mix fluid very slowly with the urine in the bladder until a predetermined intravesical pressure is reached, at which point they aspirate the mixture. The efficiencies of the various designs vary widely: some of them aspirate quite forcefully for several minutes, and others cease aspirating as soon as the slightest resistance is encountered. Unfortunately, tests of some of the latest designs show that they aspirate very feebly, and they are therefore undependable when viscid material needs to be removed from the bladder.

Regardless of their efficiency, the nearest such apparatus can come to irrigating the bladder is mixing of irrigating fluid with considerable quantities of urine. In order to irrigate the bladder this mixture would have to be removed first, and then more fluid would have to be introduced rapidly into the bladder, to be followed by another aspiration of the bladder contents. In some cases irrigation will need to be multiple for maximum effectiveness, just as is the usual case when hand irrigation is used. By the incorporation of such multiple irrigation cycles into the design of such apparatus, we can be certain that the bladder is completely filled during each irrigation and that the maximum safe intravesical pressure is not exceeded, neither of which criteria is met by the ordinary technics of irrigation with a hand syringe. To my knowledge, only one design so far described is capable of irrigating the bladder in this way. Because it is a complex apparatus which has not been widely adopted, it is assumed that the authors were not referring to this type of tidal drainage and irrigation apparatus.

A standardized method for naming synthetic organ devices and bedside therapeutic apparatus is needed, for progress in this new field of therapy will be hindered by the general use of nonspecific terms such as "tidal drainage" or "tidal irrigation," especially when their efficacy is being questioned. The coining of such names will be difficult at best, and it is my hope that something better than the use of eponyms can be developed. Progress in this field will not be served by indulging in the personalities which eponyms necessitate whenever new apparatuses are described or old ones modified.

For the present I should like to recommend that apparatus be described by the use of diagrams or, where applicable, as in this case, by the use of time and pressure graphs which show the action of the apparatus under clinical trial. The latter suggestion is emphasized because my experience has shown the difficulty of estimating the action of such apparatus until it is actually being used in the care of the patient. Such graphic studies demonstrate the ineffectiveness of many types of tidal drainage apparatus; but they point the way to improved designs which more nearly replace the anatomic or physiologic defect which is exhibited by the patient. It appears possible that tidal drainage apparatus can be developed to the point where it will irrigate better and more dependably than is now possible with human labor, thereby pointing the way to removal of some of the tedium incident to the care of patients with neurogenic bladders.

Arthur E. MacNeill, M.D., Hanover, N. H.

TUBERCULOSIS

To the Editor:—In a communication to The Journal, Nov. 9, 1946 with this heading Dr. Dock states that the "absolute pressure on the cells" in the pulmonary capillaries equals the air pressure plus the weight of the blood column in the pulmonary artery. I want to point out that the total gas pressure in the alveolar cells is about atmospheric and in the venous blood of the pulmonary capillaries substantially less than atmospheric. As far as gases are concerned, no pressure is therefore exerted in the direction from the capillaries onto the cells but rather in the opposite direction. With regard to the addend in that equation, it represents only one factor of capillary pressure; the essential factors, namely, the energy of the heart contraction, arterial and venous pressure, and the width of the arterioles and capillaries, are completely disregarded in that calculation. On the basis of his equation Dr. Dock comes to the conclusion that a lowering of the pressure by 14 per cent, produced by a change in altitude, would make (according to my theory) "the entire lung far more susceptible than the apex at sea level." My explicit statement that "the curative effect of prolonged bed rest and of high altitude appear herewith in a new light" makes it clear that Dr. Dock's conclusion is entirely a sequel of his equation and not of my theory.

It is hard to see how anybody could possibly have "discarded" in the past my theory of apical predilection in adult tuberculosis for reasons conceived now for the first time by Dr. Dock "on the basis of data only recently established." It would, however, follow from those reasons that a change in altitude of 5,000 feet would make the entire lung far more bloodless than the apex at sea level.

As regards Dr. Dock's contention that my theory was based on "data chiefly from plant physiology," I should like to state that among the twenty-six data adduced in my paper (*Wien. klin. Wchnschr.* **33**:646 [July 15] 1920) only three were from plant physiology.

Ferdinand Roder, M.D., New York.

ARTIFICIAL LIMBS

To the Editor:—In Queries and Minor Notes in The Journal March 1, page 656, under the heading Artificial Limbs, you state that in larger cities there are concerns that assemble artificial limbs under their own trade mark.

This would give the reader the impression that legs are being purchased in sections, in different shapes and sizes, such as the ankle, shin and thigh, bolted or riveted together and the trade mark stamped on. This, however, is not the case because most of the concerns buy the wood in different shapes. It may be either square, hexagonal or octagonal, 1 to 3 feet long and is being cut with band or hand saw and carved with drawing knife, chisel, gouge or special tools and bored and shaped invariably by hand by men who are wood carvers. These men from experience became familiar with the shape and function of the human extremities to reproduce their shape and size. They fit the stump into this shaped timber and also apply hinges to correspond to human joints. Then the limb is reinforced with suitable material and supplied with necessary upholstering and harness attachments. Moreover, the individual who does this work should be justly referred to as an artisan. He seldom has a willing teacher, the result being that through great sacrifice and hardship he acquires the knowledge and skill to manufacture an artificial limb.

The remunerationn is far less than for other work for the amount of time it takes to acquire the knowledge and the patience one has to exercise in dealing with the customer.

This, I believe, is the main reason why higher caliber men are not found in this industry. In fact, the limbs that are being manufactured today are inferior to the ones made thirty years ago.

F. A. Ritter, Detroit.

GASTRIC LAVAGE

To the Editor:—May I comment on your editorial "Value of Gastric Lavage in Treatment of Acute Poisoning" based on the recent work of Harstad, Møller and Simesen (THE JOURNAL, March 1, p. 545)? According to these investigators gastric lavage is generally inefficient because little of the poison is recovered and because it promotes passage of the poison into the intestine and other structures. My discussion will be limited entirely to the technic of lavage.

With all due respect to the Copenhagen workers, it might be suggested that "lavage with a conventional stomach tube through an attached funnel" is hardly the way to evacuate a stomach in a hurry. No procedure based on siphonage can hope to do that. The only worse way is the use of a small tube passed through the nares. Unfortunately small caliber tubes have so widely come to replace the large tube technic for gastric aspirations, at least in this country, that many recent students do not seem to have learned the large tube technic at all. Hence my interest in writing you.

The best procedure for lavage, and I think I have tried them all, is the use of a large tube, 32-42 French, to the proximal end of which can be fitted an Ewald aspirating bulb (capacity 250 cc.). The first step is the evacuation of all gastric contents. This can be done almost quantitatively (except for the solid residues) by attaching the deflater bulb and allowing suction to do the aspiration. If the gastric content is large, several such aspirations will be required. After evacuation is as complete as possible, one begins the lavage proper by injecting a bulbful of water and then aspirating as mentioned, the alternate injection and aspiration of bulbfuls being repeated until the returns are clear. The procedure is equally safe in conscious and unconscious patients. This method is very old, but those unfamiliar with it will find it described and illustrated in my "Synopsis of Digestive Diseases," St. Louis, C. V. Mosby Company, pages 26, 27 and 47.

The proof of the efficacy of this method is obtained by weighing the patient before and after the lavage. Always there must be a loss unless the stomach is empty, when the weight will be stationary. All medical students should be trained to achieve this degree of skill.

The rest of the authors' conclusions logically follow from the technic they used. It is not surprising that only 75 per cent of 10 liters of wash fluid could be removed by siphonage, and introducing a large amount of fluid (which cannot be quickly and quantitatively recovered from the stomach) is sure to promote passage into the intestine! Furthermore, no amount of vomiting, whether induced by apomorphine or otherwise, can evacuate a stomach so rapidly, so completely and so gently as the aspiration technic described.

JOHN L. KANTOR, M.D., New York.

DANGER OF TRANSMITTING MALARIA BY TRANSFUSION

To the Editor:—I believe it would be desirable to renew a warning to medical practitioners that a danger exists in transfusing recipients from donors who have had a past malarial history.

Although I have no extensive data the transfer of infection has occurred on numerous occasions all over the country. A case reported by Sharnoff, Geiger and Selzer (*Am. J. Clin. Path.* **15**:494 [Nov.] 1945) was of particular interest because blood had been stored in a bank for eight days, yet a malarial infection was transferred. When blood is stored at low temperatures, the parasites seem to exist for a long period. The actual limits of time have not been established, but eight days would seem to be quite an interval for an active blood bank.

I have been told of a soldier who had been overseas under suppressive medication and never had had experience with malaria; yet, when his blood was used in this country many months later, a malarial infection occurred in the recipient. Such an occurrence is rather unusual now, although during the war it was seen quite frequently. Most of the men are now out of the malarious areas; hence that danger is minimized. In several thousand cases seen personally no less than a hundred men first had malaria in this country after withdrawal of the suppressive drug used overseas. One man had been off the drug thirteen months before his first attack occurred.

As a routine procedure I believe physicians should be advised never to use blood from any person who has had a past history of malaria. There is an instance in Denver where a Greek's blood was used and malaria resulted although the man had been away from Greece, where he acquired his original infection, for thirty-seven years.

All returning servicemen should be questioned closely about a pastmalarial infection. One instance occurred here in which a man was asked specifically whether he had had malaria and he replied in the negative. However, his blood was infectious for the recipient and, on requestioning, he stated that he was afraid that the patient would be denied blood needed very badly and he thought it was of no importance.

It would seem that a safe time limit for a serviceman in this country after withdrawal from the endemic malaria areas and without a past history of malaria would be two years, provided he had not used suppressive drugs in the interim.

L. T. COGGESHALL, M.D., Chicago.
Chairman, Department of Medicine,
University of Chicago.

DIFFERENT WEIGHT RESPONSES TO THE SAME PROVOCATION

To the Editor:—The week after Dr. S. Charles Freed's article on obesity appeared in THE JOURNAL (February 8, p. 369) there came under my observation a man and his wife who illustrated his statement that "personality will . . . influence the intake of food." The husband was thin, wiry and tense; the wife, plump and good natured. The man was referred to me with the history that two months previously he had begun to have epigastric pain after eating, loss of appetite, frequent nausea and weakness. He had lost 13 pounds (6 Kg.) in three weeks—from 146 to 133 pounds (66 to 60 Kg.).

Complete x-ray studies of the gastrointestinal tract and gallbladder were negative except for a diverticulum of the lower end of the esophagus. The explanation for the patient's symptoms was found when his wife told me that two months before I saw him he had had an anonymous long distance telephone call from a midwestern state informing him that his daughter was dead. Twelve years previously this girl had married against the wishes of both parents, had moved "somewhere out West" and had not kept in touch with them. An attempt to trace the source of the telephone call was unsuccessful, but detectives located the girl, who was living and in good health. She came back to visit her parents, and a reconciliation took place. Naturally both parents were under great emotional strain. While the father was losing 13 pounds, however, the mother gained 26 pounds (12 Kg.), her weight increasing from 176 to 202 pounds (80 to 92 Kg.). She admitted that when she was worried she could not help eating far more than when conditions were normal.

When the husband's x-ray studies had been completed and he was assured that he had no evidence of cancer, he was able to eat the heartiest meal he had consumed since the anonymous telephone call.

WINGATE M. JOHNSON, M.D., Winston-Salem, N. C.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, April 12, page 1169.

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 24-26. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arkansas: * *Medical Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Written.* San Francisco, July 7-10. *Oral.* San Francisco, May 10-11. *Oral Clinical Examination for Foreign Medical Graduates.* San Francisco, June 21. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Delaware: *Examination.* Dover, July 8-10. *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia: * *Reciprocity.* Washington, June 9. Sec., Commission on Licensure, Dr. George C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: * *Examination.* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Hawaii: *Examination.* Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Kansas: *Endorsement.* Kansas City, June 26. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

Kentucky: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Medical Examination.* Baltimore, June 17-20. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 10-11. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Michigan: * *Examination.* Detroit, June 9-11. Semi-Annual meeting, Lansing, June 24. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Mississippi: Jackson, June 23-24. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Missouri: *Examination.* St. Louis, May 26-28 and June 9-11. Exec. Sec., Mr. John A. Hailey, Box 4, State Capitol Building, Jefferson City.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

Nevada: *Written Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: *Examination.* Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, June 23-26. Sec., Dr. Jacob L. Lochner Jr., State Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, May 1, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, June 17-20. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Endorsement.* Portland, April 25-26. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, June 23-25. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Tennessee: Memphis and Nashville, June 11-12. Sec., Dr. Harley W. Qualls, 1635 Exchange Bldg., 130 Madison Ave., Memphis 3.

Texas: Austin, June 17-19. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Building, Dallas 2.

Virginia: Richmond, June 18-21. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., 30½ Franklin Rd., Roanoke.

Wyoming: *Examination.* Cheyenne, June 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: June 17. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: Little Rock, May 7. Sec., Mr. L. E. Gebauer, 701 Main Street, Little Rock.

Colorado: Denver, June 4-5. Sec., Dr. Esther B. Starks, 1459 Ogden Street, Denver.

District of Columbia: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: May 31. Final date for filing application is May 16. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

Michigan: Ann Arbor and Detroit, May 9-10. Sec., Miss Eloise Lebeau, 101 N. Walnut St., Lansing.

Nebraska: Omaha, May 6-7. Dir., Bureau of Examining Boards, State Department of Health, Mr. O. F. Humble, 1009 State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, May 4. Sec., Miss Marion M. Rhea, 114 E. Marcy St., Santa Fe.

Oregon: June 7. Final date for filing application is May 21. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: *Examination.* Providence, May 14. Chief, Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Substantial Compliance With Statute of Limitations Not Sufficient.—The plaintiff filed a suit for damages allegedly caused by the malpractice of the defendant physician. From a judgment for the defendant, the plaintiff appealed to the Supreme Court of Wisconsin.

Section 330.19 of the Wisconsin statutes provides that "no action to recover damages for an injury to the person shall be maintained unless, within two years after the happening of the event causing such damages, notice in writing, signed by the party damaged, his agent or attorney, shall be served upon the person or corporation by whom it is claimed such damage was caused, stating the time and place where such damage occurred, a brief description of the injuries, the manner in which they were received and the grounds upon which claim is made and that satisfaction thereof is claimed of such person or corporation. . . ." The plaintiff's complaint was served on the defendant on Nov. 29, 1941 and it was based on alleged negligence of the defendant in his treatment of the plaintiff between June 16 and Aug. 15, 1939. This was clearly not within the required two years.

The plaintiff contended that the intent of the statute is that a defendant must be given a notice to afford an opportunity to investigate the circumstances before they become stale and to preserve evidence for his defense; he argued that a substantial compliance with such intent was sufficient and that it was not necessary to observe literally the formal statutory requirements. He then cited two steps which he claimed constituted a sufficient compliance of the statute: 1. On April 2, 1940 his attorney wrote a letter to the defendant in which he stated that he had been retained by the plaintiff "relative to the institution of a malpractice action as the result of your treatment of Mr. Beyer's fractured toe. Kindly refer this matter to your insurance carrier or contact the undersigned immediately upon receipt of this letter." 2. His attorney subsequently served on the defendant an affidavit and notice for an adverse examination. At the examination the defendant testified that the plaintiff came to his office June 16, 1939 and that the next day, after an x-ray was made of the injuries, he set the bone in plaintiff's foot and prepared the cast at the plaintiff's home.

The Supreme Court said that, in view of the express and positive provision in section 330.19 of the statutes, "No action to recover damages for an injury to the person shall be maintained unless" the injured party shall give the prescribed notice of injury or serve his complaint within two years after the event which caused such injury. The required service of such notice or a complaint is a condition precedent to the right to maintain such action. Consequently a mere substantial compliance is not sufficient. The court therefore concluded that the matters relied on by the plaintiff were not sufficient to constitute compliance with the positive requirements of the statute, that there must be stated in the required notice the time and place where the damage occurred and that satisfaction thereof is claimed of the defendant, and finally that the notice must be given in the matter required for the service of a summons in a court of records. Accordingly the trial court's judgment in favor of the defendant was affirmed.—*Beyer v. Seymer, 24 N. W. (2d) 616 (Wisconsin, 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Chronic Peptic Ulcer in Patients with Diabetes.—Wood says that among 12,000 diabetic patients observed at the George F. Baker Clinic 94 had peptic ulcer. Treatment was primarily directed toward the management of the ulcer, control of the hyperglycemia and glycosuria with insulin. The diabetes in the majority of cases was mild, thus making the problem much simpler. Even in the more severe cases of diabetes, however, a program so directed has been quite satisfactory. It is necessary to provide a well balanced diet of carbohydrates, fat and protein suitable to the diabetic state, but any type of diet required for the management of an ulcer at any stage can be calculated so that it will be a good one for both diseases and at the same time provide all the calories necessary. A table gives four such diets. Standardization should be avoided; every diet should be figured according to the specific requirements of each individual, taking into consideration his metabolism, type of work and present weight. Additional vitamins should supplement each diet. A diabetic patient temporarily out of control may at first require large doses of insulin. After a period of vigorous treatment the insulin dose necessary for adequate control will usually drop and remain fairly constant at a much lower level.

Colloidal Aluminum Hydroxide Gel and Magnesium Hydroxide in Peptic Ulcer.—Jankelson says that colloidal aluminum hydroxide gel and magnesium hydroxide combination is an effective stable buffer which acts in the stomach for several hours. With this combination ulcer pain and heartburn may be controlled with smaller and less frequent doses than are required with the colloidal aluminum hydroxide gel alone. It can be continued for long periods without the danger of an acid rebound, alkalosis or aggravation of constipation.

Eczema and Essential Fatty Acids.—Hansen and his co-workers made clinical and blood lipid studies on 225 patients with eczema and 101 control subjects in order to detect evidence of a possible relationship between a disturbance in essential fatty acid metabolism and the occurrence of eczema. Serum lipid studies on many of the eczematous patients disclosed that more than three fourths of the infants and children and more than half of the adults had iodine numbers for the serum fatty acids below the mean values for the control subjects. When used as the sole form of therapy of 148 eczematous patients of various ages, addition to the diet of fats rich in unsaturated fatty acids, such as lard and certain vegetable oils, produced a favorable clinical response in the majority of the patients. The specific role of the essential fatty acids appears to be that of restoring and maintaining normal nutrition of the skin. The routine inclusion of unsaturated fatty acids in the diet, while known allergens and other irritants of the skin were avoided, was found to afford the best protection against recurrent attacks of eczema, particularly infants and young children. The use of unsaturated fatty acid containing soy bean preparations as milk substitutes appears to be beneficial to a degree greater than would be anticipated on the basis of relief from sensitivity to the milk proteins alone. Sensitivity to wheat gradually may be reduced after the addition of lard to the diet.

War Wounds of Ventricles of Brain.—Pitts says that the high fatality rate of wounds of the ventricles during the first world war was ascribed to the lack of a barrier against infection. This report deals with penetrating wounds of the cerebral ventricular system as seen and treated in an evacuation hospital. Among 108 wounds of the brain there were 16 with involvement of the ventricles. These 16 are divided into two groups, one of which includes the patients who were admitted to the hospital with signs of impending death and had short survival periods. The second group is composed of 13 operative cases with two fatalities. The operative mortality for penetrating wounds of the ventricles is two and one-half times that for penetrating wounds of the brain without ventricular involvement. Intracranial infection was not a factor in any of the deaths. Bilateral and bipolar ventricular wounds usually lead to an early fatal termination.

Chlorophyll in Wound Healing and Suppurative Disease.—Bowers records his own observations as well as those of a group of over thirty officers of the surgical service of the staff of the Winter General Hospital obtained with water soluble chlorophyll in the treatment of clean and infected wounds. The report covers more than 400 cases, representing a variety of surgical conditions. Use of chlorophyll was followd by rapid disappearance of objectionable odors and remarkable cleanliness of the wound within two or three days. Granulation tissue seemed to be of finer texture and firmer and to form more rapidly. Epithelization also appeared to be stimulated more by chlorophyll than by penicillin. No skin irritation or adverse systemic reactions have been noted, and the chlorophyll wet dressing has been much more comfortable than dressings with saline solution, boric solution or penicillin. If chlorophyll is used as a wet dressing over a week there is a tendency to overproduction of granulation tissue, so that after the wound is clean and odorless it is advocated that chlorophyll ointment gauze be used instead of the wet dressing. Chlorophyll caused cessation of pus formation in two or three days in osteomyelitis and thoracic empyema cases. In the nose and sinus cases chlorophyll had a quicker effect in stopping purulent drainage than other agents. Physicians and patients noted the bland qualities of chlorophyll even when instilled in the eye, the nose, deep intra-abdominal abscess cavities and the pleural cavity. Chlorophyll is not antibacterial and is only weakly bacteriostatic, so that its beneficial effect is exerted through stimulation of the cells of the host.

Combined Penicillin and Sulfonamide Treatment of Peritonitis.—Brown combined sulfonamides and penicillin intraperitoneally and parenterally in patients with perforated gangrenous appendicitis with peritoneal soiling and peritonitis. The author has operated on and treated by combined chemotherapy 7 patients with acute gangrenous perforated appendicitis with diffuse peritonitis. There were no deaths, and the hospital morbidity rate averaged twelve to eighteen days. Brown concludes that the combined use of sulfonamides and penicillin is justified by the increased rate of recovery and decreased secondary complications of appendical peritonitis.

Penicillin in Neurosyphilis.—This report by Koteen and his associates is based on observations of the effects of penicillin therapy in 111 patients with neurosyphilis treated in the medical service of the New York Hospital. All the patients have been followed for at least twelve months after the cessation of treatment. Six of 11 patients with dementia paralytica attained remissions of their disease. Four of the 5 patients who failed to show significant improvement were badly deteriorated prior to therapy. There was a great change in the cerebrospinal fluid abnormalities not only in those paretic patients who showed clinical improvement but also in some who failed to improve clinically. Forty-one patients with tabes dorsalis complained of a total of fifty-seven symptoms. There was subjective improvement in thirty-three of the fifty-seven symptoms after penicillin therapy. No striking improvement was observed in the objective manifestations of tabes dorsalis. In isolated examples of various clinical forms of meningovascular syphilis the therapeutic results after penicillin were comparable to those usually observed after arsenotherapy. The authors conclude that the administration of penicillin for a two week period produces a striking effect on the cerebrospinal fluid abnormalities and certain of the clinical manifestations of late neurosyphilis. It is believed that the penicillin therapy of neurosyphilis (exclusive of primary optic atrophy) approaches and may equal fever therapy in effectiveness.

Technic for Testing Hypertensive Patients Preoperatively. J. L. Southworth and H. I. Russek.—p. 119.

Surgical Treatment of Angina Pectoris.—Saccomanno and his associates determined on dogs that stimulation of isolated spinal nerves produced cardiac acceleration and a rise in systemic blood pressure when the second through the sixth thoracic spinal nerves were stimulated. No change in heart rate or blood pressure was observed when the eighth cervical or first thoracic spinal nerves were stimulated, indicating that these segments do not convey cardiac efferent fibers. The effect on pulse rate was greatest in the second and third thoracic nerves, with diminishing effect in the fourth and fifth and very slight effect below the fifth thoracic nerve. The effect on systemic blood pressure was more or less constant from the second thoracic down to the seventh thoracic nerve. By means of surgical removal or alcohol injection of the second, third and fourth thoracic sympathetic ganglions on the affected side a complete alleviation of anginal pain and a reduction of coronary vasospasm should result.

Traumatic Pancreatitis.—Shallow and Wagner say that within the past four years 28 cases of acute pancreatitis have been encountered in the Jefferson Medical College Hospital, 20 of the edematous type and 8 of the hemorrhagic type. A conservative nonoperative treatment was generally employed, operation being reserved for the complications. One case is unique in that it followed a nonpenetrating upper abdominal injury. Sustained extremely high serum amylase values were observed and recovery took place without complications following conservative therapy. Trauma accounts for approximately 2 to 4 per cent of cases of acute pancreatitis. Following an upper abdominal injury, acute pancreatitis should always be suspected. Suspicion of traumatic pancreatitis should be confirmed by the serum amylase test. Nonoperative management, which has greatly reduced the mortality in the usual types of pancreatitis, is advocated for cases following nonpenetrating abdominal injury, if serious injury to other organs and massive hemorrhage can be ruled out.

Scalenotomy for Scalenus Anticus Syndrome.—Tanna states that the symptoms of scalenus anticus syndrome are the result of spasm of the scalenus anticus muscle resulting in compression of the brachial plexus and subclavian artery, with the creation of a vicious circle. Pain may be experienced in the shoulder, arm, forearm or even extending into the hand. The pain sometimes extends to the cervical spine, to the scapula and to the thoracic wall. The pain may be of the acute, lancinating type or dull or aching. Sympathetic nervous involvement is manifested by vasomotor spasm, lack of capillary action in the fingers and reduction of temperature, which frequently simulates Raynaud's disease. Conditions from which it must be differentiated are cervical rib, cervicodorsal sympathalgia, Raynaud's disease, subacromial bursitis, supraspinatus tendon rupture and brachial neuritis. The author reviews 11 consecutive cases of scalenus anticus syndrome for which scalenotomy was done. The results have been excellent. Seven of these cases were not associated with a cervical or abnormal rib, indicating that the scalenus anticus syndrome occurs with much greater frequency than the cervical rib syndrome. Scalenotomy may not be necessary in mild cases.

*Pathologic Changes Resulting from Administration of Streptomycin. C. W. Mushett and H. S. Martland.—p. 619.

Penicillin and Endameba Histolytica.—Knoll and Howell observed in in vitro studies that penicillin had little or no effect on cultures of Endameba histolytica, either the trophozoites or the cysts. By inference it seems probable that the improvement observed in the clinical symptoms of patients with amebiasis under penicillin therapy must be due to the action of the drug on the secondary bacterial invaders of the tissues.

Pathologic Changes Resulting from Streptomycin.—Mushett and Martland found that the parenteral administration of highly purified as well as average streptomycin samples resulted in fatty metamorphosis of the liver in monkeys and dogs. Large doses of streptomycin concentrates produced small foci of necrosis in the livers of dogs. Fatty metamorphosis was observed less often in the kidneys, but albuminous detritus appeared in the subcapsular spaces and the tubules of the kidney in some of the monkeys. Hyaline and granular casts, epithelial cells and occasionally blood cells were seen in the sediment of the centrifuged urine of dogs receiving large doses of streptomycin concentrates. Focal tubular necrosis occurred in the kidneys of 1 dog. The fatty change observed in the liver and the kidney was found to be reversible. Slight normocytic anemia also disappeared on cessation of dosage. Prolonged administration of streptomycin concentrates of average purity resulted in neurotoxic effects in dogs, but streptomycin samples of higher potency did not produce neurotoxic symptoms in dogs.

Physical Therapy in Traumatic Paraplegia.—Guttmann gives an account of methods of physical readjustment practiced in a center caring for over 160 patients with spinal injuries. Physical therapy in paraplegic patients has two aims: (1) prevention of contractures and atrophy in the paralyzed part of the body and (2) adaptation therapy of normal parts of the body. The significance of the overdevelopment of muscles which can compensate for the loss of the paralyzed muscles is discussed. Swinging, dressing and balancing exercises have proved invaluable in the mobilization of compensatory mechanisms for the postural adaptation of paraplegic patients. Games, especially wheelchair polo, play an essential part in the physical restoration of persons with traumatic paraplegia.

Schistosomiasis Japonica.—Winkenwerder and his associates review the observations made on 364 cases in the epidemic of schistosomiasis japonica which began soon after the reoccupation of Leyte in October 1944. The first patients developed symptoms one month after the landing on the island. The outbreak reached its peak in January, then gradually subsided, and came to an end in May. In the pretreatment stool examination, mature ova were found in 344 cases. Only immature ova were found in 16 cases, in which after treatment had been instituted mature ova were found. All patients were treated with an antimony compound: fuadin, antimony and potassium tartrate (tarter emetic) or anthiomaline. Only the results obtained in the treatment of 210 patients given a total dose of 40 cc. of fuadin are reported in detail. Ova disappear from the stools usually between the tenth and sixteenth days of treatment with fuadin. The viability of the eggs appears to be unaffected by fuadin, and their disappearance from the stools is probably attributable to the effect of the drug on ovulation in the female worm. The symptoms of acute schistosomiasis subside at approximately the same time at which the eggs disappear from the stools. Following one course of 40 cc. of fuadin relapses have been encountered in approximately 40 per cent of the cases. In only 4 of 55 relapses were symptoms of schistosomiasis noted. In all other cases the relapse was characterized solely by the reappearance of ova in the stools. The tendency to relapse appears to be related to the severity of the initial illness. Relapses are more likely to occur in those who have a persistent eosinophilia following the first course of treatment. The finding of intestinal nodules on sigmoidoscopy may be helpful in detecting a relapse; they occur in the absence of ova in the stools. Only 2 of the patients exhibited mild toxic effects during treatment with fuadin. Doses up to a total of 80 cc. in a single course have been administered without serious toxic effects. The therapeutic effect of these larger doses cannot be analyzed until a later date.

Laryngotracheobronchitis.—Morgan and Wishart discuss the disease which in the last decade has been termed, almost universally, laryngotracheobronchitis. The term is at best a diagnosis of convenience to describe cases presenting the same initial clinical picture. An analysis was undertaken of 549 cases. The series does not include cases of laryngeal diphtheria, but it does include cases of spasmodic croup. Sixty-nine per cent of the cases occurred under the age of 2 years and only 5 per cent over 6 years. The bacteria isolated were Streptococcus hemolyticus, Staphylococcus aureus and the pneumococcus. Hemophilus influenzae was infrequently found. Many infections were due to a virus. These were recognized by the lack of response to antibiotic drugs, failure to demonstrate pathogenic bacteria in the cultures, a normal leukocyte count or a leukopenia and a fairly typical clinical course. Antibiotic drugs are of value in prophylaxis and should be exhibited in every case of simple spasmodic croup. Tracheotomy should be performed early, but subsequent bronchoscopic suction must be frequently resorted to. Intubation cannot be recommended. The postoperative management requires experienced nurses and the constant attendance of a trained bronchoscopist. The principal causes of death are failure to relieve obstruction, overwhelming toxemia, postoperative infection, pneumothorax and mediastinal emphysema. Most deaths were in children under 4 years of age. Hyperpyrexia is a serious prognostic sign. The mortality rate has been gradually reduced in the last twenty years.

Circumcision and Venereal Disease.—Wilson collected information regarding previous circumcision on 1,304 consecutive patients at a Canadian army venereal disease treatment center. One thousand recruits at an army reception center were examined to determine the incidence of circumcision among Canadian army personnel. The figures obtained show that 76.7 per cent of the venereal disease group were uncircumcised, whereas in the control group 52 per cent were uncircumcised. The most striking difference is in syphilis, in which 90 per cent of the patients were uncircumcised. It is considered unlikely that the uncircumcised are significantly more promiscuous. Discussing the possible causes of the higher incidence of venereal disease in the uncircumcised, the author says that in gonorrhea it could be due to the fact that the foreskin, after coitus, retains infectious mucus. Here is an ideal environment of moisture and warmth, the organisms multiply and provide heavy contamination of the adjacent urethral mucosa. That syphilis is more common in uncircumcised soldiers seems even more reasonable, since tears and abrasions of the foreskin provide a port of entry for the spirochete.

Circulating Antitoxin in Diphtheria.—Ipsen determined the antitoxin titer of 425 patients with laryngeal diphtheria. Of these 287 were unvaccinated, 32 vaccinated once and 106 vaccinated with more than one injection. In the vaccinated the course of the disease was distinctly milder than that of the unvaccinated, while the antitoxin titer was much higher for the former than for the latter. When the unvaccinated are divided into groups according to the severity of the disease there is only a slight difference in the antitoxin titers of the groups. When all the cases are grouped according to the antitoxin titer there is a scarcely demonstrable difference in the course of the disease for groups with a high titer and those with a low titer. Comparison of antitoxin titers in patients having diphtheria with those in the rest of the population revealed fewer with a titer higher than 0.1 antitoxin unit among patients with diphtheria. In further statistical studies the author found a single quantity as an indicator for the course of the disease for each patient. The average course of each group can then be computed as the mean of the course of the individual cases. This provides greater statistical certainty than an analysis of the percentage of complications.

Mumps Orchitis.—Nixon and Lewis say that 101 of 339 soldiers with mumps developed orchitis. In 68 the orchitis was of sufficient severity to warrant operation. Early surgical treatment of mumps orchitis is of value in promptly relieving pain, nausea, vomiting, backache and fever, shortening the period of disability and preventing subsequent atrophy of the involved testis. Without operation the acute symptoms of mumps orchitis will disappear more gradually, requiring three to four additional days of hospitalization, and testicular atrophy will result in 40 to 60 per cent. Observations in this series suggest that the atrophy is not caused alone by the inflammation of the parenchyma and the resistance offered by the firm tunica albuginea but that the tunica vaginalis also is involved in the development of increased pressure with resulting necrosis. It is believed that early drainage of the hydrocele fluid is necessary to avoid subsequent atrophy of the testis and that early incision of the tunica vaginalis is sufficient to insure optimum results.

Grain Mite Infestation of Urinary Tract.—Crance presents 3 cases of grain mite infestation of the bladder. Entry probably occurs as the result of direct contact of infected fecal material with the urethra. However, in the male this is hardly possible, and it has been suggested that the eggs may reach the bladder through the kidney and ureters and hatch the mite after implanting themselves on the bladder wall. The fact that, according to the meager literature, infestation with the mite is about as frequent in males as in females is more or less against the direct contamination theory but rather in favor of the theory that the eggs proceed through the intestinal tract, thence to the kidney and downward into the bladder. In the reported cases favorable therapeutic results were obtained with bladder irrigations followed by instillations of mild protein silver.

Penicillin in Syphilis.—Among 75 patients with early syphilis given penicillin 2 had serologic and 3 had clinical (mucocutaneous) relapses. One of the latter group, a pregnant woman with secondary syphilis, had been treated with 1,200,000 Oxford units of penicillin. At the time of delivery of a normal appearing infant the mother's serologic reaction was positive. The serologic reaction in the infant was negative until the third month, when it became positive. At that time both the mother and the infant presented cutaneous lesions suggestive of secondary syphilis. The incidence of severe reactions in penicillin treatment is insignificant, but the Herxheimer reaction was ted in 75 per cent of patients with early syphilis; this, however, does not call for discontinuation of therapy. In order to prevent masking of syphilis, it seems necessary to subject patients receiving penicillin for gonorrhea to a six months follow-up study for syphilis. Hill says that any patient who has gonorrhea and shows an early Herxheimer reaction, evidenced by a rise in temperature after the first injection of penicillin, should be examined for syphilis.

*Some Hematologic Observations in Silicosis. H. Heimann.—p. 470.

Occupational Dermatoses in Aircraft Workers.—Ellis says that in an aircraft plant employing about 40,000 workers 235 persons were referred during 1944 and 1945 for examination of various dermatoses, which were suspected of being occupational in origin. Of these 133 proved to have nonoccupational dermatitis; 81 were considered to have occupational dermatitis; 21 had contact dermatitis of undetermined origin. Primary irritants were the cause of the eruption in 36 of the 81 patients with occupational dermatitis. Contact dermatitis was the cause in 24; in 20 of these the dermatitis was due to chromates. In about one fourth of the cases of occupational dermatitis the disease was due to chromates. Contact dermatitis due to chromates is usually an acute, weeping, crusted dermatitis involving the exposed parts and with occasional generalized dermatitis. Nummular lesions similar in form to nummular eczema developed in some of the patients. The eyelids were involved in 8 of the patients who had a contact dermatitis due to chromates. Hardening to chromates does not develop in workers sensitive to chromates. Patch tests with 5 per cent solution of sodium chromate and with the dry painted metal elicited reactions of similar degrees of positivity.

Hematologic Observations in Silicosis.—Heimann reports hematologic observations on 65 persons with silicosis with and without superimposed infection. He found that the disease was associated with a rise in the number of young polymorphonuclear leukocytes, a rise in mean corpuscular hemoglobin and an increased rate of erythrocyte sedimentation. In simple silicosis as well as in silicosis with infection there is a shift to the left of the polymorphonuclear leukocytes and an increase in the rate of the erythrocyte sedimentation. These data suggest that neither an abnormally increased sedimentation rate nor a shift to the left of the polymorphonuclear leukocytes in silicosis necessarily indicates that pulmonary infection is present as a complication of the fibrotic condition of the lungs.

Antibacterial Substance from Lichen Ramalina Reticulata.—According to Marshak, Ramalina reticulata, sometimes called California Spanish moss, is a lichen of the family Usneaceae which grows as an epiphyte along the west coast of North America. The plant has no integument but does contain in the interstices between hyphae and algal cells a carbohydrate substance which is very hygroscopic. The carbohydrate, when separated from the plant, is an excellent medium for the growth of many types of bacteria. A crystalline substance has been isolated from the lichen Ramalina reticulata, with a melting point of 191 to 192 C. and an empirical formula of $C_{17}H_{14}O_{6}$. It can be administered subcutaneously in oil daily for three weeks at a rate of 10 to 20 mg. for each 350 to 400 Gm. of guinea pig without obvious toxic effects. When so administered to guinea pigs infected intraperitoneally with human tubercle bacilli of the strain $H_{37}RV$ it appears to retard the progress of the disease.

Disseminated Pulmonary Calcification.—High and his associates collected 113 instances of disseminated pulmonary calcification and studied the skin reactions to tuberculin and histoplasmin. Of 108 patients who received both tests, 104, or 96.3 per cent, reacted to histoplasmin, while only 4 had negative reactions to this antigen. None reacted only to tuberculin, but a few reacted to both antigens. The authors think that there is strong evidence that disseminated calcifications are not frequently caused by tubercle bacilli but probably by the agent producing sensitivity to histoplasmin.

Roentgen Diagnosis of Duodenal Ulcer.—Brown and Harper state that the fluoroscopic and roentgenographic study of the stomach and duodenum in the right lateral horizontal position has proved to be useful in arriving at a more accurate knowledge of the condition of the duodenum than can be obtained from the frontal projection alone.

Radiation Therapy in Cancer of Breast.—Kaplan and Rosh's patients belonged to three groups: those who come directly into Bellevue Hospital for a primary breast condition, those referred by other hospitals or physicians for irradiation following surgical procedures or for irradiation for recurrences or metastases, and those sent for custodial care. This report covers an additional 603 cases, bringing the total for a twenty year period to 833. The authors conclude that irradiation is a valuable adjunct to surgery in the treatment of breast cancer. The best results are achieved after early diagnosis, with preoperative irradiation, surgery and postoperative irradiation. Surgery should follow within three weeks after preoperative irradiation has been administered. X-ray therapy administered after surgery is of value in alleviating distress and in prolonging life. Endocrine therapy has proved of little value in the control of breast cancer or its metastases. Since breast cancer associated with pregnancy offers a poor prognosis, the authors advocate sterilization of young women with breast cancer.

Subacromial Bursitis.—Olin thinks that trauma is the cause of subacromial bursitis in the great majority of cases. In minor injuries x-ray examination affords little or no information. With fractures of the greater tuberosity, or comminuted fractures of the head of the humerus, there is a possibility of subsequent involvement of the bursa. The gap in the contour of the greater tuberosity left by a tear of the supraspinatus tendon invariably involves the bursa. As the condition grows older, calcium deposits occur in the bursal sac. These vary in size from fine granules of sand to large irregular calcium deposits which may fill the sac beneath the deltoid muscle and even extend to that portion beneath the acromion process. The presence of calcareous deposits in the soft tissue usually form the main criterion for an x-ray diagnosis. Stereoscopic views and oblique projections may be necessary for better visualization. In many cases roentgen therapy directed to the bursa will relieve the acute pain.

Evaluation of Thiouracil in Treatment of Hyperthyroidism. M. N. Foote.—p. 23.

Pentothal-Oxygen-Curare.—Davison and Letton have compiled the pertinent facts of 609 major operations in which pentothal-oxygen-curare anesthesia was used. For comparison they also compiled statistics on a corresponding group of patients given pentothal alone. The addition of curare diminished the amount of pentothal used by 19.3 per cent, thus allowing patients to undergo even the largest operations without the attendant dangers of deep anesthesia necessary without curare. The authors prefer the synergistic effects of pentothal-oxygen-curare in abdominal surgery over spinal, cyclo, nitrous ether or local, either alone or in combination with other agents, including curare, for the induction is rapid, the effects pleasant for the patient—postoperative complications are lowered, the danger of explosion minimized and postspinal headaches eliminated. Curare should not be used in myasthenia gravis or when the anesthetist cannot give artificial respiration. The inexperienced user of curare should proceed with the utmost caution. Curare is a valuable adjunct to anesthesia when muscular relaxation is necessary.

*So-Called Triple-Symptom Complex of Behcet. E. W. P. Thomas.—p. 14.

Sulfa-Combination—A New Chemotherapeutic Principle.—Frisk and his associates discuss the problems connected with the application of the "sulfa-combination principle." The mixture prepared according to this principle is "sulfadital" and contains the three compounds sulfathiazole, sulfadiazine and sulfamerazine. The authors describe the results of a number of experiments illustrating the practicability of the method. The importance of the sulfa-combination method is twofold: It appears to eliminate the risk of concrement formation at a normal dosage and makes it possible in cases with more resistant bacteria to increase the dosage considerably without greater risk of calculus formation than is possible with a single compound.

Behcet's Syndrome.—Thomas points out that Behcet in 1937 described a hitherto unrecognized morbid entity in which grave eye disease occurs in association with peculiar ulcers of the mouth and external genitals. The clinical picture is dominated by the eye lesions, which range from conjunctivitis and corneal ulceration to hypopyon uveitis and may lead to total blindness. The eye involvement may precede, coincide with or follow the oral and genital manifestations. The two eyes may be affected simultaneously, but more usually only one eye is involved for a while; after a variable interval the other eye shows similar changes. The ulcers of the mouth and genitals are small and discrete, either aphtha-like or nodular and necrotic. A similar combination of symptoms had been reported earlier by Whitwell in 1934 and Nishimura in 1935. The author describes a case which he thinks is the first to be reported in Britain.

*Pleurisy Due to Amebiasis. L. B. Carruthers.—p. 12.
Jaundice in Acute and Severe Infections in the African. M. Gelfand. —p. 15.

Pleurisy Due to Amebiasis.—Carruthers states that a plastic pleurisy or pleurisy with effusion without involvement of the lung, associated with amebic hepatitis and not necessarily with abscess of the liver, is a common occurrence, the amebic hepatitis often being of such a mild nature as frequently to be overlooked. A series of 5 representative cases is reported to bring out the salient facts on which the diagnosis of this syndrome can be based. The important diagnostic points are the presence of liver enlargement, of liver tenderness to heavy fist percussion, of a history suggestive of amebic colitis or of Endameba histolytica in the stools, of the presence of an irregular, sluggish or high right diaphragm on fluoroscopy, and the absence of any indication of tuberculosis. The author thinks that any of these findings in the presence of pleuritis or of pleurisy with effusion justifies a trial of antiamebic therapy for the treatment of the pleuritis.

Toxicity of Streptomycin.—Madigan and his associates report the results obtained from the examination of animals and man of the pharmacologic effects of 17 batches of streptomycin. This material, though of varying purity, was free from histamine-like substances and, with one exception, antidiuretic substances; moreover, a simple relation has been found between potency and toxicity. This is in contrast to the observations previously published, which difference may be attributed to biologic variations which exist in the preparation of natural antibiotics, much as the choice of medium and the method of extraction. A graph relating toxicity and potency reveals the presence of a hitherto uncharacterized substance more toxic than pure streptomycin. This may be a toxic material present in low concentration or a second streptomycin of acute toxicity to mice. Fourteen patients have been treated systematically with these batches. The toxic manifestations were trivial.

Cerebral Beriberi (Wernicke's Encephalopathy).—De Wardener and Lennox point out that Wernicke described in 1881 fatal cases of ataxia, ophthalmoplegia and clouding of consciousness which he called acute superior hemorrhagic polioencephalitis. Subsequent descriptions emphasized the association with alcohol. From 1933 onward a deficiency origin began to be suspected, and more recent clinical and experimental work has pointed to vitamin B_1 deficiency as the principal factor. There were 52 cases of Wernicke's encephalopathy in a Japanese prisoner-of-war camp; 30 of the patients recovered. The early diagnosis, based on anorexia, vomiting, nystagmus and emotional changes before the onset of gross mental and eye changes, is emphasized. Early treatment with thiamine injections cured rapidly and completely. Acute thiamine deficiency appears to be the sole cause of the syndrome. The name cerebral beriberi is suggested.

*Further Report of Epidemic of Acute Polyarthritis. G. Goswell.—p. 861.
Surgical Ballistics. F. V. Stonham.—p. 863.

Epidemic of Acute Polyarthritis.—Goswell says that during the past few years attention has been drawn to a condition characterized by painful, swollen joints, lymphadenitis and a transient exanthem, to which the term "acute polyarthritis" has been applied. Outbreaks occurred among troops stationed in the north of Australia. The author reviews observations on 51 patients, of whom he was one. Six weeks beforehand, in the Darwin area, several cases of what was at first believed to be dengue were recorded; but as the condition developed it was considered that these also were cases of acute polyarthritis. The outbreak commenced suddenly, 34 cases developing within the first ten days. All 51 had been recorded within thirty days. The possibility of this being an insect borne disease was considered, but no definite indications were found. The duration of the illness ranged from a few days to several weeks. More than 90 per cent of the men receiving treatment as outpatients had completely recovered by the seventh day. In a number of cases, however, residual stiffness persisted. In all except 1 case this stiffness had cleared within four weeks.

*Recent Experiences with BCG Vaccination in Norway. G. Hertzberg. —p. 1.
Tuberculosis in Egypt. M. S. Abaza and A. Sami.—p. 10.

BCG Vaccination in Norway.—Hertzberg says that from 1940 on when war and occupation engulfed Norway, most authorities on tuberculosis felt that greater use should be made of BCG vaccination. Records show that between 42,000 and 43,000 people were vaccinated in Norway during the war, but the correct figure is probably nearer 60,000, since many doctors omitted to send in their returns. Tuberculin-positive results were commonly reported to be as low as 50 per cent among the BCG vaccinated. Investigations on the cause of this decline are presented. The Norwegian war tuberculin from the end of 1943 and up to the present time seems a little weaker than the prewar tuberculin. This drop in potency is too small to be of statistical importance if one uses the strong Mantoux test with 1 mg. of tuberculin; on the other hand the weakening is of practical importance when tuberculin tests are carried out, using only the weak test, a single Pirquet test. Those who, in their control of the BCG vaccinated, use only the Pirquet test must be disappointed with their positive results. Although BCG vaccination does not give 100 per cent protection against tuberculosis, it does give from 75 to 90 per cent protection. Its use is justified in conjunction with other measures in the campaign against tuberculosis.

*New Investigations on Notalysine, a Factor Distinct from Penicillin. Suzanne Hutter.—p. 1138.

Niemann-Pick Disease and the Lipoidoses.—Pfandler reviews observations on 14 members of a family in which 2 brothers died with Niemann-Pick disease at the ages of 29 and 33 years respectively. These cases demonstrate that Niemann-Pick disease is not exclusively a disease of infants and young children. A genealogical tree of the family illustrates diagrammatically the various forms in which Niemann-Pick disease became manifest. Eight members exhibited microsymptoms indicative of a disturbance in the lipoid metabolism. Hepatosplenomegaly with phosphatides can persist in the latent stage and cause little disturbance. The author believes that the latent forms of Niemann-Pick disease are possibly more frequent than is generally believed. The transmission of the disease seems to be irregularly dominant, with a tendency to more pronounced manifestation in the male sex. The primary cause of the disease is obscure.

New Investigations on Notalysine.—Hutter described in a previous report the phenomenon of staphylococcic lysis by filtrates of Penicillium notatum Westling. This bacterial lysis has been attributed to a substance designated as notalysine, which is elaborated by the fungus when it has a medium that is rich in yeasts and buffered by phosphates. The substance is insoluble in acetone and alcohol, partially soluble by chloroform and sulfuric ether and completely soluble in petroleum ether. Although the available information about notalysine does not permit its chemical identification, results so far indicate that it should not be confounded with penicillin. Penicillinase has no antagonistic effect whatever on notalysine. Notalysine is an initiator of bacteriolysis, considered by the author an antemortem anticipation of autolysis. The coordination of the play of enzymes, a sign of life, can perhaps be broken by a failure of one of the coordinated factors. Science has not yet identified this failure. It is possible that the recognition of its antagonist, the initiator of bacteriolysis, will contribute to this identification and bring the first light into the obscure problem of cytolysis.

Syndrome of Mikulicz. M. Sepulveda R.—p. 691.

Hepatobiliary Complications of Typhoid During Childhood.—Sepulveda de Borquez and Fuentes Acevedo say that among the 225 cases of typhoid treated in a children's hospital between 1941 and 1946 icterogenic hepatitis was present in 10 and acute cholecystitis in 3. One of the latter was accompanied with angiocholitis. Four of the cases of icterogenic hepatitis appeared during the first fifteen days of typhoid. In 3 of these the complication did not greatly influence the course of the typhoid, which was rather mild. The jaundice and hepatomegaly which characterized the complication were mild and disappeared in from eight to fifteen days. In 1 of the cases death occurred a few hours after hospitalization. In the remaining 6 the complication appeared after the fourth week of typhoid. This group of cases of hepatitis in the convalescence of typhoid was usually characterized by long duration and greater severity than the cases of the first group. Laboratory tests revealed increased bilirubinemia in all cases in relation to the degree of jaundice. In cases in which liver tests were made, impaired function was evident. Treatment consisted in a carbohydrate regimen in which sugar solution was given by injection and by mouth. In some cases liver extract was given and in others choline syrup.

Dextrocardias. C. Viviani C., G. Dussaillant G. and E. Bellolio.—p. 681.
Statistical Study of Tuberculous Meningitis. J. Schwarz.—p. 691.

Blood Proteins in Infectious Hepatitis.—Armas-Cruz and his associates studied the total protein content and the albumin and globulin fractions in 29 normal serums and in 111 serum specimens from 84 patients with infectious hepatitis. They found that during the infectious stage of hepatitis there was no significant variation in the total protein figure; there was a slight decrease in the albumin figure and a clear augmentation in the quantity of globulins; that is, there was an inversion of the albumin-globulin quotient. There is a relationship between the intensity of the flocculation of the cephalin-cholesterol emulsion, the colloidal gold reaction and the figures for blood protein, serum albumin and globulin and the albumin-globulin quotient. Although the relationship between these factors is not exact, in cases in which the albumin-globulin quotient is greatly altered the flocculations are usually more pronounced than when the albumin-globulin quotient is normal or only slightly changed.

Curious Histologic Aspect of Thyroid in Presence of Undifferentiated Epithelioma of Lung. Z. Marinello Viudaurreta.—p. 715.

Vi Antigen in Treatment of Typhoid.—Fernández Brito and his associates used the Vi antigen prepared by the technic of Luippold in a concentration of 2,000 units per cubic centimeter on alternate typhoid patients, those with uneven numbers being treated with the antigen and those with even numbers serving as controls. In the 71 cases treated with from two to five injections of 0.1 cc. they observed psychic improvement and some shortening of the febrile period. The mortality was

4 per cent in those injected with the Vi antigen and 15 per cent in the controls. Treatment with progressive doses of the antigen resulted in detoxication of the patient, regardless of whether the patient was treated early or late. In those treated early the febrile period was shortened. The total number treated with the progressive doses was 56; their mortality was 3.57 per cent.

*Medullary Hypoplasia (Agranulocytosis). C. Alvarez and T. C. Minnhaar.—p. 542.

Medullary Hypoplasia (Agranulocytosis).—The subject of this report was a man aged 50 who was normal up to the age of 48, when he began to suffer from articular pain and icterus, and he became easily tired and rapidly lost weight. The spleen was enlarged. A diagnosis of agranulocytosis was made as a result of the hematologic examination and the examination of medullary material obtained by sternal puncture. The treatment consisted in administration of injections of liver extract, iron and arsenic preparations and vitamins. The blood improved in the course of the therapy but, a final intercurrent infection occurred. The disease in the reported case seemed to be due to chronic silver nitrate poisoning from the use of a hair dye by the patient.

*Amaurosis in Perforated and Bleeding Duodenal Ulcers. D Forgarasi. —p 716
Late Sequels of Oral Lesions Caused by Caustic Substances. P. Adler and I Jakabfi —p. 717.

Amaurosis in Perforating and Duodenal Ulcer.—Forgarasi observed blindness in a man aged 49 with bleeding and perforated duodenal ulcer. The patient had had gastric disturbances almost constantly since 1940. Blindness following loss of blood has received little attention in the surgical literature, but the ophthalmologic literature reports a considerable number of such cases. In men, usually of the fourth and fifth decade of life, it is generally hemorrhages in the gastrointestinal tract that are responsible for this form of blindness. In women, however, this form of amaurosis is usually observed after profuse loss of blood incident to childbirth or abortion. Amaurosis has been observed also after venesection. The degree of visual disturbance varies, but loss of vision is usually complete. For the treatment blood transfusions have been recommended, but also liver and iron preparations as well as acetylcholine and strychnine. The prognosis is usually unfavorable

*Dermatitis Among Workers Employed in Citrus By-Product Industry. M. Seidmann.—p. 39.

Dermatitis in Citrus Industry.—Seidmann says that workers who come into contact with the different parts of citrus fruits may develop paronychia, necrosis or dermatitis. Paronychia develops because the juice and the moisture foster the growth of fungi, which are probably the causative agent. Necroses or "holes" are slowly healing ulcers, seen among those engaged in peeling. Here there is the double effect of cutting with the knife and the caustic action of the juice and of the peeling. Discussing dermatitis, the author says that the most important part from the standpoint of irritation is the extract of the peel, i. e. the ethereal oil. Observations reported here were obtained in visits to factories and fruit groves and in studies on 40 cases of dermatitis. It is most prevalent among young people, women and European Jews. The texture of the skin seems to be a factor. As to the kind of fruit, most of the cases were among those coming in contact with lemons; second in order were bitter oranges, then grapefruit and finally oranges. Those handling the peels and employed in the expression of the ethereal oil are most affected. The author further discusses the varieties of eruption, the results of patch tests on patients d protective measures.

*Increasing Chemoresistance in Gonorrhoea. O. Nørgaard.—p. 123.

Tuberculous Primary Infection of Genitalia.—The first of the 2 cases of primary tuberculous infection of the genitalia reported by Bjørnstad concerned a previously Pirquet negative woman aged 21 in whom tubercle bacilli were found not only in the pus from an inguinal fistula but also in a lesion on the left labium. She had had intercourse with a man who had tuberculous epididymitis. The second patient was a man aged 32 who had been Pirquet negative. He developed a swelling of the lymph nodes in the right groin and two weeks later a slightly indurated preputial ulcer. His wife had a tuberculous salpingo-oophoritis, and her menstrual blood was found to contain tubercle bacilli. The author stresses that the possibility of tuberculous primary infection ought to be considered in obscure cases of genital ulcer with involvement of the regional lymph nodes.

Increasing Chemoresistance in Gonorrhea.—Nørgaard reviews the Scandinavian literature on chemoresistance in gonorrhea. He finds that practically all authors agree that chemoresistance is increasing in the Scandinavian countries. He reports observations in 1,487 cases of gonorrhea that were treated with sulfathiazole in the outpatient department of Rudolph Bergh's Hospital in the years 1944, 1945 and 1946. It has been found that for the past three years there has been no further increase of the chemoresistance; it now remains stationary, in men at 60 to 65 per cent and in women at 45 to 50 per cent. Chemotherapy gives better results in women than in men. Chemotherapy gives better results in older than in younger persons.

*Neostigmine in Treatment of Muscle Spasm in Rheumatoid Arthritis. T. Wramner.—p. 241.

Bronchial Asthma Caused by Sulfathiazole.—Rosberg reports the histories of 2 nurses, both of whom were exposed to sulfathiazole powder in the course of their daily work. Both developed typical attacks of asthma. At the same time eosinophilia could be registered in the blood. Epicutaneous tests with sulfathiazole were negative, but positive reactions were obtained with 2-aminothiazole hydrochloride (in both cases) and acetylsulfanilchloride (in 1 case), substances probably formed by the decomposition of the sulfathiazole in the organism. These reactions are possibly caused by a sensitization of the skin for these elements. There exists, however, also a possibility of allergy to a whole group of chemically related elements.

Neostigmine in Muscle Spasm in Rheumatoid Arthritis.—Wramner investigated the relaxing effect of neostigmine on muscle spasm in 25 patients with rheumatoid arthritis and associated conditions. The neostigmine was administered subcutaneously in doses of from 0.25 to 1.25 mg. once daily. In 21 of the 25 patients there resulted a decrease in muscular pain, muscle rigidity and pain on movements, and an increase of mobility was observed. The effects appeared within ten to twenty minutes after the subcutaneous injection and lasted up to fourteen hours. Neostigmine probably causes this effect by depressing the motor cells of the anterior horn.

Book Notices

The X-Ray Treatment of Accessible Cancer. By D. Waldron Smithers, M.D., D.M.R., Director of the Radiotherapy Departments, The Royal Cancer Hospital (Free) and the Royal Free Hospital, London. Cloth. Price, $8.50. Pp. 147, with 116 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This book is a first edition written by a well known English radiologist and therapist. The author has selected those cancers which are easily accessible for direct irradiation with roentgen rays, namely cancer of the skin, genitalia, mouth and other body cavities, and those in sites rendered accessible by surgical exposure, excluding the breast. He shows wise discretion in such a selection, for this is one branch of roentgen therapy in which the results are beyond question. The author emphasizes the point that, although some cases of accessible cancer should be treated by irradiation alone and others by surgery alone, there are many others in which irradiation and surgery complement each other. He also mentions that radium may be of equal value in some of the conditions described but confines his discussion entirely to the use of roentgen rays.

The author presents a concise and comprehensive description of the equipment and apparatus available at present for the treatment of accessible cancer. He also details the classification, staging, records and assessment of results of therapy. The procedure of biopsy, particularly serial biopsy, during treatment, with special reference to cell counts, is evaluated both for the given case under treatment and for future use in determining the response of various tumors to irradiation so that eventually a more definite tumor dose may be established for these cancers.

The author's grouping of accessible cancers according to their locality rather than their histologic origin will be a helpful and handy reference in everyday practice. The text covers the parts of the body where accessible cancers are found, including in each description the frequency of various types of cancer in each locality, the clinical diagnosis, differential diagnosis, pathologic and histologic findings, the treatment of each type and evaluation of results of treatment.

The chapter on the use of roentgen therapy in the treatment of cancers made accessible by surgical exposure lays open to the imagination the future possibilities for treatment by direct irradiation of these previously "internal," inaccessible cancers. The inadequacy of treatment of internal cancers has not been entirely the resistance of the tumors to irradiation but the inability to deliver sufficient irradiation without irreparably injuring normal tissues. There are also technical difficulties, particularly the difficulty of directing the incident beam so that it correctly falls on the tumor under treatment.

The book contains a summary of the literature and descriptions of the generally accepted technics. Among its finest features are its illustrations in colored and black and white reproductions showing lesions before, during and after treatment. It well deserves a place in the library of every therapist.

Peptic Ulcer: Its Diagnosis and Treatment. By I. W. Held, M.D., F.A.C.P., Attending Physician, Beth Israel Hospital, New York, and A. Allen Goldbloom, M.D., F.A.C.P., Assistant Clinical Professor of Medicine,. New York Medical College and Flower-Fifth Avenue Hospital, New York. Cloth. Price, $6.50. Pp. 382, with 110 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1946.

The selection of the title for this book is probably unfortunate. While peptic ulcer is a convenient term, it does not convey a precise meaning. The foreword states that the phrase as used includes ulcers found in that portion of the intestinal tract extending from the esophagus to the jejunum inclusive as well as in Meckel's diverticulum. But as might be expected the greater portion of the book is devoted to a discussion of ulcers of the duodenum and stomach. The distinction between gastric and duodenal ulcer should be sharply drawn. It is better to speak of duodenal ulcers and benign gastric ulcers as two separate entities. There is, of course, no place for the medical management of a malignant ulcer, a fact which in itself sets off the ulcer in the stomach from that in the duodenum. The authors also divide ulcers into simple and complicated types. Since the catastrophes due to ulcers are ordinarily the results of complications regardless of the site, the choice of this division is therefore not the best. The use of the term "catarrh" for gastritis is unscientific.

The subject matter is divided into chapters on pathogenesis, pathology, diagnosis and treatment. Roentgen diagnosis is well described. Various forms of medical treatment of ulcer are thoroughly discussed. Surgical treatment is briefly outlined, including the complications. The writers minimize the importance of removing the pylorus, and one feels that the concepts of surgical treatment of the past decade are not well presented. Thus there is no mention of vagotomy. Some errors are noted. The insulin effect on the vagus centers will increase rather than decrease gastric acidity. There is nothing mysterious about the tetany associated with vomiting in severe pyloric obstruction. It should be presented as a straightforward alkalosis tetany, and it does not carry with it a mortality of seventy per cent in spite of treatment. The modern knowledge of fluid and electrolyte replacement deserves a more scientific elucidation. The clinical experience of the authors is evident, and there is much of wisdom in their description of the clinical phases of the problems associated with ulcers.

With the passage of sufficient years since x-ray diagnosis of ulcers of the stomach and duodenum became established, the medical management of these lesions has come to need a thorough statistical analysis. Then we may have answers to the questions What is the recurrence rate of medically treated ulcers? and What is the incidence of complications following supposedly adequate medical management? Then the rationale of treatment, whether medical or surgical, can find itself on a firm basis.

The Cultivation of Viruses and Rickettsiae in the Chick Embryo. By W. I. B. Beveridge and F. M. Burnet. Medical Research Council, Special Report Series No. 256. Paper. Price, 2s. Pp. 92, with 10 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1946

This publication is a revision and amplification of a previous monograph by one of the authors (Burnet) published in 1936. It constitutes therefore a helpful though brief review of published results of the use of the chick embryo method during the intervening period of ten years. The introductions to the two monographs are quite similar, covering mainly the history of the method, the management of eggs before inoculation, development of the embryonic membranes of the chick and procedures for inoculating the chorioallantois. In addition, the present report describes several new methods of inoculation that have been usefully employed by various investigators for special purposes, including procedures for amniotic, allantoic, yolk sac, intravenous, intracerebral and other routes of inoculation. Likewise successful inoculations of human skin, amnion and chorion grafted on the chick chorioallantois, especially for studies of certain viruses to which the chick embryo is insusceptible, are described. The twelve pages of references, in contrast to the one and one-half pages of the first publication, indicate the numerous contributions that have been made by means of the chick embryo method during the past decade. The authors refer to these accessions adequately though briefly in their chapter (v) on the cultivation of individual viruses and rickettsias.

Ten years ago Burnet listed fifteen viruses that had been successfully cultivated in the chick embryo. In the present report the cultivation of thirty-seven viruses is described, including in the late additions such agents of human disease as the viruses of smallpox, yellow fever, rabies, St. Louis and Japanese B encephalitis and mumps. The usefulness of the method for preparing vaccines is emphasized, especial attention being devoted to vaccines against influenza, yellow fever, equine encephalomyelitis, fowlpox and laryngotracheitis of fowls—now processed extensively from infected chick embryos. In the 1936 report brief reference was made to successful cultivation of the rickettsias of typhus and Rocky Mountain spotted fever in the chorioallantois. In the meantime the method of cultivation by inoculation of the yolk sac was developed by Cox and by this means a variety of rickettsias can now be grown in quantity, and vaccines from this source have been prepared against epidemic and murine typhus, Rocky Mountain spotted fever, Q fever, boutonneuse fever and Tobia fever. The development and use of these methods is adequately treated. In the earlier treatise, except for a brief mention of the cultivation of the micro-organism of bovine pleuropneumonia, no consideration was given to the cultivation of bacteria and other micro-organisms in chick embryos. In the intervening period the method has been extended to studies of infection by bacteria, fungi and protozoa. As a result, early stages of infection by such microorganisms as Hemophilus pertussis, Bacterium tularense, the Brucella strains, Pasteurella pestis and meningococcus have been studied in investigations of pathogenesis.

Recently the causative agent of granuloma inguinale (Donovania granulomatis) was grown by yolk sac inoculation and identified for the first time by Anderson. Brief accounts of these applications of the chick embryo method are included in the report. The authors have not been sufficiently impressed by the importance of histologic, and especially cytologic, aspects of lesions induced in embryos by the various agents used, and in this respect nothing more has been contributed by the present publication than was contained in Burnet's monograph of 1936. The question is still left in doubt by the authors as to the regular occurrence in embryonic lesions of specific intracellular inclusions in such infections as vaccinia and herpes simplex, in which careful studies have demonstrated these structures in characteristic detail.

Since publication of the monograph under consideration there has appeared the important series of studies by Dr. Shope and his associates concerning the cultivation of the virus of rinderpest in developing hen's eggs and the preparation of an effective vaccine from this source by means of an attenuated strain of the virus resulting from repeated egg passages. The great importance of the chick embryo for studies of pathogenesis and for elucidating the cell-parasite relationship receives little or no consideration, but the extensive bibliography will be very helpful to those who wish to use the chick embryo method for experimental investigations.

Ernährungsprobleme in Mangelzeiten: Die schweizerische Kriegsernährung 1939-1946. Von Prof. Dr. med. Alfred Fleisch, Ordinarius für Physiologie und Direktor des Physiologischen Institutes an der Universität Lausanne. Cloth. Price, 32 Swiss francs. Pp. 518, with 35 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10, 1947.

This book summarizes the nutritional experiences of Switzerland from 1939 to 1946 as seen by the national commission on wartime food controls. While the text is in German, each of the fifteen chapters includes a summary in French. In addition to a priceless fund of quantitative facts there are interesting discussions of the psychology of rationing, black markets, rich and poor refugees, and so on. The facts corroborating Hindhede's controverted report that about 60 Gm. of protein is an adequate daily allowance for adults are summarized on page 269. Statistics on diabetes are analyzed and lead to the conclusion (p. 381) that the incidence of this disease is influenced more by income level than by any other factor. Facts and explanations regarding the undeniable decrease in dental caries in children during the war are summarized on pages 459-463. The foregoing examples have been taken at random to illustrate the interesting and important nature of the contents; there are few theoretical or practical areas in the field of nutrition that are not enriched by the facts which the author presents, and no physiologist or biochemist can afford to remain in ignorance of this work.

Scoliosis: The Practical Approach to Treatment. By Beatrice Woodcock. Cloth. Price, $2. Pp. 111, with 50 illustrations. Stanford University Press. Stanford University, California; Oxford University Press, Amen House, Warwick Square, London, E. C. 4, 1946.

This is a small, compact, cloth-bound volume generously illustrated with photographs, line drawings and x-rays. The author is a physical therapist whose interest in the subject of scoliosis was stimulated years earlier while she was director of physical therapy at the University of Iowa, under the direction of Dr. Arthur Steindler. The mechanics of scoliosis is explained in terms that are easily understood. The plan of treatment by exercises is based on this interpretation of the reason for the rotation and lateral curvature of the spine which is characteristic of the deformity. Although the book will be of greatest value to students and to physical therapists, there is much to be found in it which the average physician, who is daily dealing with patients affected with scoliosis, will either have never learned or have forgotten. It should be noted that x-ray record 1 a in the appendix is upside down. Otherwise this book has been refully edited.

Pharmacology and Therapeutics. Originally Written by Arthur R. Cushny, M.A., M.D., LL.D. Thirteenth edition by Arthur Grollman, A.B., Ph.D., M.D., Professor of Medicine and Chairman of the Department of Experimental Medicine, the Southwestern Medical College, Dallas, Texas, and Donald Slaughter, B.S., M.D., Dean of the Medical School, University of South Dakota, Vermillion. Cloth. Price, $8.50. Pp. 868, with 74 illustrations. Lea & Febiger, South Washington Square, Philadelphia 6, 1947.

For forty-eight years Cushny's textbook in pharmacology has been recognized as one of the authoritative works in this field. The last edition prepared by Professor Cushny was the eighth, which appeared in 1924, and subsequently four editions were prepared by the Anglo-American team of Professors J. A. Gunn and C. W. Edmunds. The last edition prepared by them appeared in 1940, and the death of Professor Edmunds and the resignation of Professor Gunn necessitated the appointment of new editors. That the choice of these editors was a happy one is evidenced by the high quality of the present edition.

Because of the rapid advance of the science of pharmacology during the past seven years, the text had to be thoroughly rewritten, much old material deleted and even more new material added. The present editors succeeded in making this extensive revision without destroying the fundamental approach to the subject which was characteristic of the original author and, indeed, one can surmise that this revision is exactly in line with what Cushny would have wished.

Although all sections of the book have undergone some revision, those which have been most completely rewritten include the metals, bile and bile salts, alcohol, anesthetics both general and local, barbiturates, ergot alkaloids, hormones, vitamins, quinine and other antimalarials, hydroxyquinoline derivatives, sulfonamides, and the serums and vaccines. Among the new sections added are those on carbon monoxide, helium, BAL, meperidine hydrochloride (demerol, isonipecaine), anticonvulsants, analeptics (which were included under "volatile oils" in the twelfth edition), di-isopropyl-fluorophosphate, new sympathomimetic drugs, thiouracil, hematics, including heparin, dicumarol and fibrin products, new antimalarials, new sulfonamides, penicillin and other antibiotics, and new anthelmintics.

A number of minor criticisms and a few major ones may be directed at the present edition. One serious error was noted on page 184, where the dose of Mapharsen is given as 0.6 Gm. and which should read 0.06 Gm.

It is questionable whether the subject of counterirritation and the preparations used for this purpose deserve ten pages of text which could be well devoted to more important subjects. The discussion of the treatment of acute alcoholic intoxication includes the recommendation for strychnine injections, which are of questionable value, but omits mention of the use of the newer analeptics such as Metrazol, Amphetamine or desoxyephedrine. Nine pages are devoted to a discussion of the actions of strychnine, although the authors acknowledge its lack of therapeutic value in any of the conditions for which it has been proposed. Why, then, devote so much space to a useless drug?

The section on pentnucleotide leaves the impression that it is of value in agranulocytosis, but most authorities have concluded that it is ineffective. Furthermore, in discussing the treatment of agranulocytosis in the section on antipyretics, the authors neglect to recommend the most valuable form of treatment, namely the use of massive doses of penicillin.

The section on the sulfonamides could, perhaps, be improved by laying more stress on the adverse reactions and sensitization following local use of the drug, and on the rapid development of drug-resistant strains of organisms, particularly in the treatment of gonorrhea. The use of "units" in discussing streptomycin dosage is unfortunate, since as early as the fall of 1945 all market packages of the drug were labeled in terms of weight.

It is surprising that more information on Benadryl and Pyribenzamine is not to be found in the text, particularly in view of the good discussions on other drugs such as BAL and D.F.P., about which information was made available only recently.

Despite the criticisms offered, the volume is a valuable and competent revision of a standard textbook. Furthermore, it has the distinct advantage over other well known textbooks in pharmacology of being completely up to date. The book is printed on excellent paper and is attractively bound. It can be recommended as an excellent textbook for teaching and reference.

The Use of Research by Professional Associations in Determining Program and Policy. By Esther Lucile Brown, Director, Department of Studies in the Professions, Russell Sage Foundation. Paper. Price, 25 cents. Pp. 39. Russell Sage Foundation, Publication Department, 130 East 22d St., New York 10, 1946.

Not all of the policies and activities of an effective, progressive professional association can be determined at the conference table. Nor can they be determined solely by salaried professional staffs. The need for sound planning and careful research by a trained research staff is emphasized in this brief review, which deals principally with the methods, or lack of methods, by which the most important functions of professional organizations are carried on.

At present the main phases of association activities in which research is an important factor are professional education, enlargement of professional service, salaries and personnel policies, and structure and function of the associations. The greatest progress in research has been made in the field of professional education as exemplified in the studies made by the American Library Association, the American Association of Dental Schools and the American Medical Association. Standards of education have been raised and improved through the efforts of organizations such as these, by means of intensive research into the educational situation in their respective fields.

The author emphasizes the need for better research into the service aspect of the organization with greater stress being put on the expansion of professional service to meet more fully the needs of the population. Coordination and cooperation with comparable associations in related professions is also urged as a necessary field for study and research.

This pamphlet presents a candid view of professional associations, noting their inadequacies, commending their accomplishments and pointing out means of developing their activities and influence through scientifically planned programs. As a critical analysis it should be brought to the attention of all professional association staff members.

Experimentelle Grundlagen zu einer modernen Pathologie: Von der Zellularzur Molekularpathologie. Von P. Busse Grawitz. Cloth. Price, 32 Swiss francs. Pp. 359, with 126 illustrations. Benno Schwabe & Co, Klosterberg 27, Basel 10, 1946.

In this monograph the author describes experiments which, he thinks, refute some of the fundamental concepts of Virchow and Cohnheim with respect to the origin of cells of inflammation. By means of tissue culture or by implantation of tissues into animals, particularly tissues coated with collodion, he arrives at the conclusion that there are humoral forces which determine cell growth or regression, either stimulating or inhibiting. The book contains 120 photomicrographs and 6 colored plates, which serve as a basis for the author's conclusions. Various technics are described for the study of cellular changes which may help to elucidate obscure problems of histology and pathology, particularly the problem of cancer. The monograph will be of interest to those who wish to explore the possibility that cells do not necessarily arise from other cells but may arise from connective tissue ground substance or even from tissues from mummies.

Principles in Roentgen Study of the Chest. By William Snow, M.D., Director of Radiology, Bronx Hospital, New York. Fabrikoid. Price, $10. Pp. 414, with 508 illustrations Charles C Thomas, 301-327 East Lawrence Ave., Springfield, Illinois, 1946.

This employs a slightly different pattern from that of the conventional textbook. The descriptions of the lesions are given in a short and abbreviated style, much as one would prepare an abstract. The author has not attempted to consider any of the excellent contributions to the study of chest diagnoses nor has he considered many of the accepted physiologic and pathologic concepts in arriving at the chest diagnoses. He does consider briefly bronchial spasm, carbon dioxide tension and lung circulation. As one studies the book the lack of reference material is apparent. The illustrations, some of which are good and some poor, have very short legends and the majority of them do not include a history. One feels the need for illustrations made in views other than many of those included. The lack of emphasis on differential diagnosis is felt throughout. Likewise the author does not include any consideration of the contribution of body section roentgenography in the diagnosis of obscure lesions. The arrangement of many of the illustrations is most unusual. Those that are arranged symmetrically are pleasing to the eye but those that are offset and which stick out into the margin are quite unusual. The index does not refer to any of the illustrations, and on turning to the subject matter one often does not find an illustration of the subject of discussion. A number of the illustrations are excellent, but there are some which do not show the lesions that the author wishes to demonstrate, and this is in spite of the fact that both space and size of illustrations are adequate.

Principles of Anatomy and Physiology for Physical Training Instructors in the Royal Air Force. Great Britain, Air Ministry, Air Publication 3125. Cloth. Price, 7s. 6d. Pp. 180, with 158 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1946.

This book attempts to explain important principles of anatomy and physiology having a direct relationship to the Royal Air Force physical training program. The approach to the problem is functional, with emphasis given to the kinesiology involved. Chapters I, II and III are devoted to the fundamental anatomy of bones, muscles and joints, while chapter IV is concerned with the basic physiology having rather direct bearing on exercise. In the remaining portions of the book one chapter is given over to a discussion of posture and corrective exercises, breathing, fitness for flying, general fitness, the instructor's part in rehabilitation and questions commonly asked by instructors. The book is essentially of manual type, having the specific purpose of furnishing a condensed overview of what a professionally prepared physical educator in this country would get in a number of undergraduate courses. Anatomy, physiology, kinesiology, physiology of exercise and corrective and adapted activities are all touched on. The majority of American teacher training institutions commonly offer these subjects as at least semester courses in the professional physical education curriculum. The section devoted to rehabilitation of surgical and medical cases describes the place of graduated exercise in the remedial program. The relations of the supervising physician and the instructor are discussed, and the need for careful and individual handling of men in various stages of illness and recovery from injury is stressed. The manual is well printed and illustrated and presents basic principles in concise form. It should prove useful in situations in which needs exist similar to those evidently found among the Royal Air Force physical training personnel.

Vitamins and Hormones: Advances in Research and Applications. Edited by Robert S. Harris, Professor of Biochemistry of Nutrition, Massachusetts Institute of Technology, Cambridge, Massachusetts, and Kenneth V. Thimann, Associate Professor of Plant Physiology, Harvard University, Cambridge, Massachusetts. Volume IV. Cloth. Price, $6 80. Pp. 406, with illustrations. Academic Press, Inc., 125 E. 23d St., New York 10, 1946.

This is the fourth volume of a series of publications on vitamins and research that has provided a useful reference source for those who seek advanced knowledge. The books are not for those who would only glimpse casually the fund of knowledge now opened by research on endocrinology and vitaminology but for those who want thorough reviews of the more intricate problems related to these special fields of science. Included in volume IV are discussions of the newer hemopoietic factors of the vitamin B complex, nutrition and resistance to infection, manifestations of nutritional deficiency in infants, effect of B vitamins on the endocrinologic aspects of reproduction, nutritional therapy of endocrine disturbances, the thyroid and diabetes, thyroactive iodinated proteins, the protein anabolic effects of steroid hormones, and methods of bioassay of animal hormones.

The chapters are well oriented and instructive and the contents presented in an interesting style in spite of somewhat voluminous detail. Each chapter is supported by many references and is divided into logical subheadings. While they will be read, unfortunately, essentially only by specialists, teachers and research workers, the discussions provide information that is of value to practically all medical students and to most practitioners. The use of vitamins and endocrines in modern medical practice requires constant study because of new concepts and advancing knowledge. Such books as the present serve a useful and helpful role by providing a source for obtaining up to da and more than casual information.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF MYASTHENIA GRAVIS

To the Editor:—A patient with myasthenia gravis is getting neostigmine methylsulfate (by injection) and the bromide orally; also ephedrine. I wonder if there is anything else with which to supplement the treatment? A study of the obscure etiology suggested the use of calcium ascorbate intramuscularly to detoxify (the disease may be due to some unknown toxin) and the use of acetylcholine with or without thiamine (it may be due to a defect at the neuromuscular junction). Please give precautions to be taken, if any, when acetylcholine and thiamine are given simultaneously. Would administration of aminoacetic acid and partly predigested proteins (proteolysate, amigen) along with pyridoxine (they say pyridoxine is essential to insure a normal amino acid metabolism) be of any use?

M.D., Michigan.

ANSWER.—Neostigmine bromide in divided doses of 15 to 30 mg. each is the most efficient treatment at the present time for myasthenia gravis. The drug is usually taken by mouth, spaced throughout the day and night. For some patients neostigmine in the form of the methylsulfate as a supplemental measure is needed. The methylsulfate form is given by intramuscular injection in doses of 0.5 to 1.5 mg. Ephedrine sulfate 24 mg. is also of considerable value in the treatment of myasthenia gravis. The average dosage of the combined neostigmine and ephedrine for ambulatory cases is about ten to twelve tablets of neostigmine bromide (15 mg.) and two to three tablets of ephedrine sulfate (24 mg.) in a period of twenty-four hours. Usually the drugs are taken every two to three hours from 7 a. m. to 11 p. m.; occasionally one or two tablets may be needed at 2 a. m.

Ephedrine sulfate was the chief drug used in the treatment of myasthenia gravis before the introduction of neostigmine, and many patients were maintained in a state of reasonable health by this drug alone. It is now almost exclusively used as a secondary medication to neostigmine, being about 10 per cent as efficient as the latter drug. Ephedrine sulfate, when taken by mouth, tends to fortify, prolong and smooth out the action of neostigmine bromide. It may be given either by capsules or as tablets. Ephedrine is usually given before noon, as it frequently causes insomnia if given later in the day. Three pills of 24 mg. each is the ordinary dose, but it may be used in smaller amounts four or five times a day. Since 1935, when neostigmine bromide was first introduced, many other drugs have been used. None except ephedrine have been as efficient as neostigmine in overcoming the muscular weakness in myasthenia gravis.

Guanidine hydrochloride may be used in doses of 125 mg. three or four times a day by mouth. Toxic symptoms such as nausea, abdominal cramps, muscular twitching and paresthesias, particularly of the lips and fingertips, are not infrequently encountered. After many months patients may become more tolerant to the drug and many or all of the untoward symptoms will disappear. The drug may be used alone with a moderate degree of efficiency. When used as a supplemental drug to neostigmine, guanidine is of value in about 5 per cent of the cases treated. It is thus somewhat less effective than ephedrine sulfate. Some patients use it exclusively.

Potassium salts, like guanidine, increase the sensitivity of muscle to acetylcholine. Clinically the salts tend to prolong the effect of neostigmine, but only when used in large doses. Patients may require 10 to 12 Gm. three times a day, an amount that cannot be tolerated easily by most persons. Because the drug causes gastric distress and urinary frequency, most patients prefer not to take it over any considerable period of time. It is somewhat more palatable when added to a mixture of egg and milk.

Aminoacetic acid (glycine) in doses of 10 Gm. three or four times a day is ineffective. Even larger doses have not been of value. The drug does not have a place in the treatment of myasthenia gravis.

Calcium ascorbate, proteolysate, amigen, pyridoxine and thiamine have not been given special mention in the literature on myasthenia gravis.

Di-isopropyl-fluorophosphate produces less improvement in myasthenia gravis than does neostigmine. The dose must be limited because of the toxic effects of the drug. Two to 3 mg. intramuscularly may be given once or twice a week to supplement the effect of neostigmine.

Acetylcholine and the other derivatives of choline, acetyl-beta-choline (mecholyl) and carbaminoylcholine (doryl), are unsuitable for clinical use because of their transient and variable effects. They have a similar parasympathomimetic effect to neostigmine, but when given orally the results are uncertain and if used subcutaneously the drugs are not easily controlled. The toxic effects are quickly overcome by the intravenous use of 0.5 to 1.0 mg. of atropine. Neostigmine is so far superior to acetylcholine, mecholyl or doryl in the treatment of myasthenia gravis that these drugs are no longer used except in experimental investigations.

Many endocrine preparations have been tried in the treatment of myasthenia gravis without affecting either the symptoms immediately or changing the natural course of the disease. The anterior pituitary hormones have been fully investigated, as well as thyroid and thymus extract and adrenal cortical substances. The adrenotropic factor in the anterior pituitary is now under clinical trial. As myasthenia gravis shows a strong tendency to spontaneous remissions and relapses, fluctuations in relation to menstruation and pregnancy and some hypothetical relation to the thymus gland, an endocrine factor in the disease is reasonably certain. No therapeutic measures, however, based on endocrines have been sufficiently promising to justify their continued use. Thymectomy too has been disappointing. Some relief has been afforded to a few patients, usually consisting in their ability to be adequately maintained on less neostigmine than before the operation. In a few instances thymectomy has been followed by complete remission; in many, no change has occurred. Patients are not made worse by thymectomy, but the operative mortality is high (10 to 25 per cent) and the results are so equivocal that fewer operations are now being done than three or four years ago. Patients with thymomas did not do better after thymectomy than persons with normal or slightly hypertrophic glands. Complete remissions of spontaneous origin, moreover, are not unknown in the natural course of the disease, thus making any evaluation of treatment, medical or surgical, a hazardous procedure.

FLUORESCENCE OF NAILS

To the Editor:—It has been reported (Ginsberg, Julius E., and Shallenberger, Paul L.: Wood's Light Fluorescence Phenomenon in Quinacrine Medication (The Journal, July 6, 1946, p. 808) that following discontinuance of quinacrine therapy the characteristic greenish yellow fluorescence exhibited by the nails beneath Wood's light disappears last from the nail of the great toe. Can this be explained on the basis of differential rates of growth of the various toenails, or is an additional factor involved?

W. Q. Wolfson, M.D., Chicago.

ANSWER.—The explanation of this phenomenon is believed to be on the basis of the different rates of growth of the different nails. The fluorescence appears to disappear from the proximal portion of the nail within a month or two after quinacrine is stopped. As time goes on this clear proximal portion becomes greater and gradually results in a fading distal fluorescence. It is felt that if absorption of quinacrine from the nail had occurred, the fading process would have involved the entire nail instead of having its origin and end result as reported.

It seems to have been established in human beings that there is some gradation of growth rate in the various nails of the body and that the great toe, being the largest nail and usually the thickest, probably has the slowest rate of growth. In addition to the foregoing comments, the inquirer may be interested in referring to a previous article on this subject entitled "Unusual Pigmentation Developing After Prolonged Suppressive Therapy with Quinacrine Hydrochloride," by Lutterloh and Shallenberger (*Arch. Dermat. & Syph.* **53**:349 [April] 1946). In this study the deposits of quinacrine were observed to remain in relatively the same spot where they originally occurred. The interpretation of this was that the pigment had been deposited in the nail bed rather than in the nail itself. It was accordingly believed that the fluorescence is a phenomenon of diffuse drug distribution while the pigmentation is most likely a result of periodicity and irregularity in the amounts of drug dosage. In other words, the fluctuation of the drug dosage of from one to ten tablets a day would result in widely different heights of blood level, saturation and resultant pigment deposit.

EFFECT OF DRUGS ADDED TO ALCOHOLIC BEVERAGE

To the Editor:—1. What are the probable effects of adding a barbiturate to an alcoholic drink (i. e., doping a whisky and soda)? 2. What might be the expected results if a drink (alcoholic) was doctored with ¼ grain (0.016 Gm.) of a hypodermic tablet of morphine sulfate? morphine tartrate syrette? cocaine? 3. What might be the expected result if the doctoring agent was acetylsalicylic acid? 4. Are there any simple tests to determine what agent might have been used in a case of suspected doping of an alcoholic drink with a small quantity of the "doctoring agent" (to differentiate those listed in 1, 2 and 3)?

Capt. John E. Newland, M. C., United States Army.

ANSWER.—It is difficult to answer these questions specifically since the total dosage of the drug ingested and the quantity of alcohol imbibed are variants which influence the end result.

There is no satisfactory evidence to indicate that the addition of any of the substances mentioned to whisky and soda (the average 6 ounce [180 cc.] drink, representing a 10 to 15 per cent hydroalcoholic solution) would significantly alter the ordinary pharmacologic action of the various compounds. The soluble barbiturates and the salts of morphine and cocaine would dissolve and contribute a bitter taste to the solution which could be detected by the experienced drinker. Acetylsalicylic acid would dissolve with difficulty but would be more difficult to detect.

The barbiturates and morphine would summate with alcohol to contribute to its depressant effect at any level of dosage of the drug or quantity of alcohol imbibed and hence to reduce the quantity required to paralyze respiration.

In a general way cocaine would tend to antagonize the depressant effects of moderate quantities of alcohol and would contribute to the excitement stage. Any large quantity of this drug would contribute to cardiovascular failure because of its cardiotoxic action.

Acetylsalicylic acid in moderate quantities (up to 1 Gm.) would not have any characteristic additive or antagonistic action to alcohol. In large quantities it would probably contribute to an early circulatory collapse in the drunken state.

A simple, accurate chemical test for the substances in question is not available. Unless the correspondent is prepared to conduct rather elaborate chemical procedures, details of which may be found in any standard work on toxicology, it would be well to place the suspected material in the hands of a competent toxicologist, especially if such a case might have mediocolegal implications.

HYPNAGOGIC HALLUCINATIONS

To the Editor:—A young woman of a somewhat tense and nervous disposition complains of flashes of light or occasionally vivid visual hallucinations of faces or scenes which are prone to occur in the drowsy state which precedes sleep. This disturbance occurs especially when there has been much nervous stress and strain during the same day. Physical examination is negative. Please discuss the nature and significance of this phenomenon.

M.D., Illinois.

ANSWER.—Hallucinations are mental impressions of sensory vividness that occur without known external stimulus. They are distinguished from illusions, which are similar impressions depending on misinterpretations of an external stimulus.

Hallucinations may be psychogenic or physiogenic in origin. They may occur in toxic states and in brain lesions but most commonly are psychogenically induced. Hallucinations may occur on rare occasions in normal people.

The patient described in the query appears to have hypnagogic hallucinations that characteristically occur in the state just between sleeping and waking. They usually have an accompanying sensation of drowsiness, a characteristic dreamlike quality, and the person who experiences them usually realizes their hallucinatory nature. These are apt to occur at some time in the life of any persons and generally may be said to have psychologic significance similar to that attributed to dreams.

VENESECTION AND HYPERTENSION

To the Editor:—I should like an opinion with regard to venesection (500 cc.) in cases of essential hypertension. Is it ever indicated prior to the appearance of congestive failure with pulmonary edema? Is it ever used as a prophylaxis against impending cerebral hemorrhage?

M.D., Pennsylvania.

ANSWER.—Venesection in hypertensive disease is rarely indicated and frequently is emphatically contraindicated. In acute congestive heart failure with venous hypertension and pulmonary edema phlebotomy of 500 cc. may be a life saving measure as a temporary expedient while oxygen inhalation apparatus is being obtained and before rapid digitalization is possible. As criteria for determining impending cerebral hemorrhage are not adequate, venesection cannot be justified as a prophylactic measure. In the rare instances of arterial hypertension secondary to polycythemia vera, repeated venesections are legitimate and often useful.

Arterial hypertension, with the single rare exception of that associated with polycythemia, is not due to an abnormally large blood volume but to arteriolar constriction, either spastic or arteriolarsclerotic. In many instances hypertension is associated with anemia, often of considerable degree. In such cases therapy to correct the anemia commonly results in considerable reduction of the hypertension. Obviously, further exacerbation of such anemia by venesection is undesirable. The chronic damage done by hypertension arises from interference with the nutrition and respiration of parenchymatous cells. In hypertensive crises with anginoid pain or evidences of cerebral ischemia, vasodilating drugs are both safer and more effective than venesection. The hypertensive patient needs all the oxygen carrying capacity that an optimal hemoglobin content can give him.

INFECTION OF BARTHOLIN GLAND

To the Editor:—A married woman aged 40 has an acute cystic condition of the bartholin gland about ¾ inch (1.9 cm.) in diameter and 1½ inches (3.8 cm.) in depth. There is no history of trauma, and the patient denies any venereal history. The patient states that she had a hard dry stool, which caused her to do much straining in evacuating the bowel. The swelling of the bartholin gland appeared about four hours after straining took place. The patient was given 400,000 units of penicillin in divided doses in the first twenty-four hours after the swelling was noticed. This caused an immediate subsidence of all symptoms, except that the mass remained about the same in size. Would this quantity of penicillin sterilize the cystic content? What would be the possible etiology? Is excision of the affected gland the ideal solution?

M.D., California.

ANSWER.—It would be difficult to say whether the penicillin has sterilized the cyst. Since the patient does not give a history of venereal infection it would appear that the etiology would be a nonspecific infection. The ideal treatment is excision of the cyst.

MALE SEX HORMONE IN FUNCTIONAL UTERINE BLEEDING

To the Editor:—Can you tell me the physiologic action of male sex hormone in the treatment of functional bleeding in women?

Warren A. Lapp, M.D., Cincinnati.

ANSWER.—The exact physiologic action of the male sex hormone in the control of functional uterine bleeding is not known; but there are at least two factors involved, one of which concerns the myometrium and the other the pituitary gland. In the opinion of Sturgis, Abarbanel and Nader (*Am. J. Obst. & Gynec.* **39**:102 [Jan.] 1940) the action of testosterone is first of all inhibition of rhythmic intermittent contractility, thus lessening the volume flow of blood to the uterus. Second, by its direct action on the myometrial elements the volume flow of blood in the myometrium is reduced. The net results is a diminution in the flow of blood to the endometrium, with a consequent reduction in the amount of uterine bleeding. In commenting on this article, Greenhill (Year Book of Obstetrics and Gynecology, 1940, p. 513) remarks that this theory does not take into consideration the suppression of the pituitary gland by testosterone propionate with subsequent diminution of ovarian function, which may account for the control of uterine bleeding.

VITAMIN B COMPLEX AND ESTROGENS

To the Editor:—Does vitamin B complex suppress the estrogenic function in women and will its prolonged use hasten the menopause or upset the libido?

M.D., Columbia, South Carolina.

ANSWER.—Vitamin B complex has little direct effect on the secretion of estrogens or the physiologic action of these substances. The B vitamins do, however, have a significant effect on the maintenance of the proper balance of estrogens in the body through regulating the normal metabolic functions of the liver. Thus where the liver contains insufficient amounts of vitamin B complex the metabolic destruction of the estrogens is lessened, and a relative excess of estrogens circulating in the blood stream may occur which can induce certain changes in the tissues typical of hyperestrogenism. Among these changes are hyperplasia of the endometrium, cystic mastitis, abnormal uterine bleeding, premenstrual tension and amenorrhea (Biskind, M. S.; Biskind, G. R., and Biskind, L. H.: *Surg., Gynec. & Obst.* **78**: 49 [Jan.] 1944). When vitamin B complex is administered in large doses the liver regains its normal function of metabolizing estrogens, and these conditions are corrected. The prolonged use of vitamin B complex will not produce ovarian dysfunction and therefore will not hasten the menopause. It is doubtful that the libido would be diminished by the administration of B complex.

PREVENTION OF DERMATITIS IN RUBBER MANUFACTURE

To the Editor:—Many employees complain of what they call "rubber poisoning." This is a "carry-over" of old ideas among workers. How can I minimize contact dermatitis in rubber manufacturing plants?

Floyd M. Burgeson, M.D., Des Moines, Iowa.

Answer.—"Rubber poisoning" is a term applied by rubber workers to whatever illness or dermatitis they think is due to their occupational environment. Many of these conditions are not due to rubber or its compounds, and some of them are not even of occupational origin. The criteria for making a diagnosis of occupational dermatitis will be found in Schwartz, Louis, and Tulipan, Louis: Occupational Diseases of the Skin, Philadelphia, Lea & Febiger, 1939, pages 51-61.

The prevention of dermatitis in rubber manufacture has for its theme the prevention of contact with irritant chemicals. This is accomplished by efficient general and local ventilation devices, by furnishing the workers daily with clean protective clothing and by enforcing personal and environmental cleanliness. In some instances protective ointments may be of value.

Further information is given by Schwartz and Tulipan on pages 385-386, and by Louis Schwartz (Skin Hazards in the Manufacture and Processing of Synthetic Rubber, The Journal, Feb. 17, 1945, p. 389).

BLOOD PICTURE IN LATE PREGNANCY AND PUERPERIUM

To the Editor:—What are the accepted figures for hemoglobin content and red blood cell count for women in the ninth month of pregnancy and for the first two postpartum weeks?

Erwin Neter, M.D., Buffalo.

Answer.—Dieckmann and Wegner published the best available figures for the blood constituents in normal pregnancy:

	Hemoglobin	Cell Volume	Cell Count
38 weeks gestation	12 Gm.	38.3 per cent	4.23 million
2 weeks post partum	11.9 Gm	37.7 per cent	4.44 million

They found that there is a decline in the hemoglobin per hundred cubic centimeters of blood during pregnancy, reaching a maximum of about 15 per cent at the twenty-sixth to the thirty-fifth week of gestation. There is a comparable decrease in the hematocrit, which reaches a maximum of about 14 per cent. However, the total amount of hemoglobin and the total hematocrit increase during pregnancy as a result of the increase in total blood volume.

Reference:

Dieckmann, W. J., and Wegner, C. R.: Studies of the Blood in Normal Pregnancy: II. Hemoglobin, Hematocrit and Erythrocyte Determinations and Total Amount of Variations of Each, *Arch. Int. Med.* **53:** 188 (Feb.) 1934.

EFFECTS OF VASECTOMY AND LIGATION OF OVIDUCTS

To the Editor:—Please discuss the possible injurious effects (sexually or otherwise) of tying off the vas to prevent conception and of tying off the tubes in a case in which further pregnancies are definitely contraindicated. The man in the case fears aging of his faculties; the woman knows that abdominal section is not without danger.

Paul W. Van Metre, M.D., Rockwell City, Iowa.

Answer.—The only injurious effect in doing a bilateral vasectomy is that the man becomes sterile. At one time it was thought that a vasectomy improved the libido, but now investigators have definitely established that this is not true. The same statement applies to tying off the oviducts. There are some states, however, which have laws forbidding the sterilization of men, and it would be well to consult the laws of the state before any procedure is considered.

UNDULANT FEVER AND BLOOD SEDIMENTATION RATE

To the Editor:—Please discuss the effect of brucellosis in its various forms and stages on the sedimentation rate.

M.D., Georgia.

Answer.—The data that might supply even a fraction of the answer that is implicit in this question are not available. The little knowledge that is available suggests that the results of this nonspecific test, if they were to be accumulated in sufficient quantity, would not distribute in accordance with the recognized forms and stages of brucellosis but rather with relation to the location, size, nature and state of activation of regional brucella localizations which may occur in practically any tissue or organ the body, and at any stage of any recognized clinical form disease.

FECAL FISTULAS FOLLOWING APPENDECTOMY

To the Editor:—I have just operated on a patient who presented symptoms and signs postoperatively that lead me to believe that he had a "blowout" of his appendical stump following appendectomy. The appendix was not acutely inflamed but was adherent to the cecum, with its tip buried in the posterior parietal peritoneum. More than average difficulty was encountered in removing the appendix. The stump was buried without ligation with a Parker-Kerr stitch. On the second postoperative day he developed severe pain in the operative region and symptoms of localized peritonitis. On the fifth postoperative day he developed a fecal fistula. I have decided that the buried stump of the appendix "blew out" as the result of poor circulation on the wall of the cecum due to excessive manipulation in removing the appendix. What is the incidence of this sort of complication?

Thomas W. Kredel, M.D. Indiana, Pa.

Answer.—Postoperative fecal fistulas following appendectomy have resulted from (1) vascular thrombosis and infection of the cecal wall with necrosis, (2) pressure on the intestinal wall from drainage tubes and other objects, (3) cutting off of the blood supply to the cecum by tight purse-string sutures, (4) operative difficulties resulting in necrosis of the bowel and (5) other less common causes, such as blowing out of the appendical stump, inadvertently cutting the ligature of the stump or the purse-string suture or inflammatory or neoplastic diseases of the cecum.

There are three main surgical procedures for dealing with the stump of the appendix: (1) simple ligation, (2) ligation of the stump and inversion with a purse-string suture and (3) inversion of the stump without ligation. The generally accepted figure for fistulas following appendectomy with all procedures is roughly 4 per cent. Throughout the literature series have been reported in which the figures are both higher and lower. One report of 3,000 cases showed an incidence of only 1.4 per cent. Others range up to as high as 15 per cent. In 4,655 cases Deaver reported an incidence of 4.7 per cent, but these were mainly confined to those which had perforated and had abscess formation requiring drainage.

The case outlined in the query falls into a rather special classification. The fact that the appendix was not acutely inflamed and the fact that the stump was inverted without ligation would negate some of the causes of fistula formation. Statistics on this class are rare. The figures which would fit the case most closely are reported from Lexer's clinic by Burkle-de la Camp. In 3,200 cases of appendectomy performed by inversion without ligation of the stump, no fecal fistulas developed.

ANTHOCYANINURIA

To the Editor:—Can beets, especially Harvard beets, tint or color the urine a blood red?

M.D., New York.

Answer.—The ingestion of beets occasionally may cause the urine to be colored by an abnormal pigment. This condition, anthocyaninuria, may be confused with hemoglobinuria. This pigment, an anthocyanin, can be distinguished easily from blood by the fact that it is pink in acid and yellow in an alkaline solution. According to one study (Ruh, H. O., and Garvin, J. A.: *Ohio State M. J.* **20:**763 [Dec.] 1924) young beets, because of a greater pigment content, more frequently produce this effect than old beets. Anthocyaninemia may also occur, according to the authors mentioned. Other case reports of this condition are given by:

Mathison, Abe: Anthocyaninuria, abstr. *Am. J. Dis. Child.* **51:**226 (Jan.) 1936.

HEMILATERAL PERSPIRATION

To the Editor:—What might make a man perspire on one side of his body and not on the other?

Paul R. Hahn, M.D., Racine, Wis.

Answer.—The inquirer does not state whether the entire side is affected or how long the trouble has been present; neither does he state clearly whether there is a lack of perspiration on one side or an increase on the other. If one entire side is affected, then the probability is that the trouble lies in the hypothalamus. If only part of that side is involved, especially the trunk and the extremities, the site of involvement may be with the cord. There may be an inborn developmental difficulty, in which case the sweat abnormality has been present during the entire lifetime of the individual. Under these circumstances it would be worth while to have the patient consult a neurologist. A few persons perspire freely over some localized site, usually on one side, after the ingestion of certain foods such as chocolate or nuts. Inquiry should be made concerning such relationship. Since desensitizing methods have not proved useful, the patient would have to give up any food incriminated.

The most frequently encountered reaction to sodium penicillin administered parenterally is urticaria. Other reactions affecting the skin have been described, including "id" type reactions on the hands and feet, maculopapular eruptions of various types and erythema multiforme-like lesions.[1] It is our purpose in this paper to summarize our experience concerning the incidence of urticarial reactions during and after penicillin therapy, to cite cases demonstrating the unpredictability of this reaction and to report instances in which reacting patients could, and could not, tolerate continuance of penicillin therapy by the simultaneous administration of compounds having an antihistaminic effect.

Urticaria resulting from penicillin therapy was first reported by Keefer and his associates.[2] Dawson and Hobby[3] observed 3 instances of urticaria in the first 100 patients whom they treated with penicillin. They pointed out that the allergic response to penicillin might be due to impurities in the complex mixture, but this theory has not yet been confirmed or disproved.

Our experience indicates that (1) penicillin reactions are more frequently encountered in patients who have had repeated courses of this drug; (2) some patients who have had an urticarial reaction to penicillin may tolerate further penicillin therapy, while others may not; (3) skin tests with penicillin are unreliable as a means of predicting the occurrence of reactions to penicillin on further administration of the compound; (4) antihistamine compounds, particularly Benadryl,[4] are useful in controlling penicillin urticaria, and (5) urticarial reactions may at times be persistent and severe.

Allergic reactions of various types have been noted after the administration of a wide variety of drugs, and certain principles have been established on the basis of an enormous experience in this branch of dermatology and allergy. However, these principles are often disregarded in connection with new drugs, and this disregard may expose patients to unnecessary risks or may deny them treatment which might well be given with reasonable safety. An admirable summary of reactions to drugs has recently been published by Sulzberger and Baer,[5] and a review of some of the principles outlined by them will be helpful in the management of patients with reactions to penicillin. In particular, the following should be kept in mind: 1. Almost any chemical or biologic compound has some capacity to induce sensitization of various tissues of the body. 2. A reaction noted during or after exposure to a compound may not necessarily occur on reexposure. 3. Cutaneous reactions to a drug may vary considerably in appearance, though certain drugs have a pattern reaction which is the one most likely to be noted after their administration. 4. There is a variable period of incubation between the initial exposure to the drug and the demonstration of sensitivity to it; this period is almost never less than five days but may be as long as months or years. 5. Skin tests are often unreliable indicators of the patient's ability to tolerate further administration of the drug concerned. 6. There may be a considerable delay in the appearance of an eruption due to a drug after a patient's exposure to it, and, also, the eruption may persist for some time after withdrawal of the offending compound.

The antihistamine drugs, Benadryl and, more recently, Pyribenzamine,[6] constitute valuable additions to the methods of treatment of allergic reactions in general, and of urticarial reactions to penicillin in particular. Lowe,[7] Curtis and Owens,[8] Shaffer[9] and O'Leary and Farber[10] have all found Benadryl useful in the treatment of urticaria. Further experience will be required to demonstrate the full usefulness and limitations of these compounds. We are reporting herewith only our experience with them in urticaria due to penicillin; the results with a considerable series of patients afflicted with other allergic reactions involving the skin will be summarized elsewhere.

From the Institute for the Study of Venereal Disease of the University of Pennsylvania, John H. Stokes, M.D., director; and the Department of Dermatology and Syphilology, Donald M. Pillsbury, M.D., director.

The project of which this investigation forms a part is a cooperative undertaking between the United States Public Health Service and the University of Pennsylvania; financed by a grant in aid and directed by the Penicillin Syphilis Panel of the Hospital of the University of Pennsylvania, John H. Stokes, chairman.

In the first 824 cases of syphilis treated with penicillin and followed at the Institute for the Study of Venereal Disease at the University of Pennsylvania, there were 15 cases of urticaria, an incidence of 1.8 per cent. Each of the 824 patients in this group received at least 1.2 million units of penicillin in 7.5 days or longer and returned to the clinic at regular intervals after the completion of treatment. It is our opinion that this incidence is increasing; 2 cases of urticaria were noted in the first 200 patients treated (November 1943 to August 1944), while treatment of the last 200 patients (October 1945 to May 1946) resulted in 12 cases of urticaria.

The 15 patients who had urticarial reactions all gave negative personal histories in regard to other manifestations of allergy. In 1 of these patients an urticarial eruption developed after each of his two 7.5 day courses of penicillin. In another patient there developed a morbilliform eruption on the fifth day of her first course of treatment. Seven patients acquired urticaria after the second course of penicillin, following an uneventful first course; 5 had hives during or after the third course of treatment, who had no reaction during the preceding two courses, and 1 patient tolerated three courses without incident, only to have urticaria develop shortly after the fourth course was completed.

The cases of certain patients whose varying clinical courses illustrate basic principles underlying the interpretation and management of reactions to penicillin are cited in the following reports.

REPORT OF CASES

Readministration of penicillin after a severe urticarial reaction to it may not be followed by recurrence of the urticaria on reinjection of a full therapeutic dose of penicillin.

CASE 1.—W. D., a Negro man aged 53, was under treatment for meningovascular syphilis, diabetes mellitus and hypertensive cardiovascular disease. He had no personal or familial history of allergic diseases. In the treatment of his syphilitic infection he was given 1.2 million units of sodium penicillin in isotonic sodium chloride solution over a period of eight days in November 1943; a second course of 2.4 million units in eight days in July 1944, and 1.2 million units in 7.5 days in April 1945. Considerable clinical improvement was noted, but because of a persistently positive spinal fluid, grade II, he was readmitted to the hospital Feb. 6, 1946 and received 4.8 million units of sodium penicillin in 7.5 days. Twenty-four hours after discharge on Feb. 13, 1946, there developed large urticarial wheals which were distributed over the entire body. He was readmitted to the hospital on Feb. 15, 1946. Biopsy of one of the cutaneous lesions showed a typical histologic picture of urticaria. The patient was given 100 mg. Benadryl by mouth and was entirely relieved of his pruritus in forty-eight hours. The administration of Benadryl was continued in a dose of 100 mg. orally three times a day; there were only a few wheals remaining in eight hours, and in forty-eight hours there was no evidence of urticaria. On Feb. 17, 1946 the patient was tested by the intradermal injection of 0.1 cc. of isotonic sodium chloride solution containing 1,000 units of penicillin. A zone of erythema 1.2 cm. in diameter was noted at the site of the injection containing the lot of penicillin originally administered to the patient; injection of another lot of penicillin in the same concentration produced an erythematous zone 0.5 cm. in diameter. On the same day the patient was given 1,000 units of penicillin intramuscularly, without reaction. On the following day 40,000 units were administered, without return of pruritus or urticaria.

CASE 2.—D. R., a white man aged 52, was under treatment for tabes dorsalis and received his first course of penicillin in March 1945. He was given 2.4 million units of sodium penicillin in eight days without reaction. Because of persistent tabetic pains he was readmitted in January 1946 and started on 40,000 units of sodium penicillin dissolved in isotonic sodium chloride solution every three hours. On the twelfth day, after the patient had received 3.4 million units, typical urticarial lesions developed, and there was a concomitant, cramping abdominal pain. Penicillin therapy was immediately discontinued, and Pyribenzamine, 50 mg. three times a day, was administered orally. The latter was discontinued after the second dose, because of the vomiting associated with the urticarial reaction. Large gyrate urticarial lesions were present over the entire body three days after the onset, and the vomiting continued. The patient was then given 10 mg. of Benadryl intravenously, following which he became extremely drowsy, and the urticarial lesions were less pronounced. The following morning Benadryl was administered by mouth in a dosage of 100 mg. three times a day. There was no evidence of urticaria two days later, and Benadryl administration was discontinued without recurrence of the lesions. On the sixth day after the onset of urticaria a placebo injection was given without reaction, and on the eighth day 1,000 units of sodium penicillin of the original lot was given without reaction. On the tenth day the patient received 5,000 units, then 40,000 units; the following day he returned to a dosage of 40,000 units every three hours until 1,400,000 units had been received. There was no recurrence of urticaria, pruritus or abdominal pain, in spite of the fact that he was receiving no antiallergic treatment and was being given the original dosage of the same lot of penicillin that apparently caused his allergic reaction.

It is sometimes possible to continue penicillin therapy in a reacting patient by the simultaneous administration of penicillin and an antihistamine compound.

CASE 3.—H. S., a white man aged 50, was first admitted to the hospital May 13, 1944 for treatment of tabes dorsalis. Two and four-tenths million units of sodium penicillin were administered in a period of nine days, without immediate or delayed reaction. The patient was retreated in March 1945 with 2.4 million units of penicillin given over ten days, again without reaction. Because of recurrence of lightning pains, the patient was readmitted to the hospital on March 5, 1946 for additional treatment. From this date until March 12, the patient received 40,000 units of penicillin every three hours. At 9 p. m. on that date there suddenly developed generalized giant urticarial lesions. Penicillin therapy was discontinued, and in eighteen hours the patient's pruritus had diminished but some urticarial lesions were still present. At 3 p. m. on March 13 a test dose of 40,000 units of sodium penicillin was administered intramuscularly. Severe pruritus recurred promptly, and the urticaria become more pronounced. On March 14 the patient was given Benadryl, 100 mg. three times a day by mouth, and penicillin was readministered in a dosage of 40,000 units every three hours. The urticaria disappeared, and the patient tolerated continued penicillin therapy well. On March 18, 1946, the amount of Benadryl was reduced to 150 mg. a day and the dosage of penicillin was maintained at 40,000 units every three hours. The urticaria promptly recurred, and the patient's temperature rose to 102 F. On March 19 the dosage of Benadryl was increased to 300 mg. daily, and again the urticarial lesions disappeared. On March 21 it was again reduced to 150 mg. daily, but there was no recurrence of the urticaria. On March 22 all treatment was discontinued, and the patient did not acquire hives during several weeks of observation thereafter.

Intradermal tests with solutions containing 1,000 units of penicillin in 0.1 cc. were performed. The skin showed no reaction in twenty minutes, twenty-four hours and forty-eight hours to the original lot of penicillin used or to several other lots of penicillin.

Urticarial reactions to penicillin are sometimes not controlled by the administration of Benadryl, may be accompanied by severe gastrointestinal symptoms and may be reprecipitated by the administration of small amounts of penicillin.

CASE 4.—F. M., a white woman aged 50, was under treatment for tabes dorsalis. She gave no personal or familial history of allergic diseases. The initial treatment with penicillin was administered in July 1944, and 3 million units were given in ten days without reaction. Subsequent to this treatment the patient showed considerable improvement but because of a persistently positive spinal fluid was admitted to the hospital for further penicillin therapy on Nov. 30, 1945 and scheduled to receive a total dose of 7 million units. On Dec. 9, 1945, after 5.2 million units had been administered, a generalized severe urticaria was noted, and treatment with penicillin was discontinued. Twenty-four hours later the urticaria had not improved, and treatment with Benadryl, 300 mg. daily by mouth, was started. There was no lessening of the urticaria twenty-four hours later. Shortly thereafter, abdominal pain, nausea and vomiting developed which were aggravated by the taking of any food, liquid or drug by mouth. Benadryl for intravenous administration was not available, and the patient was treated with epinephrine hypodermically, calcium gluconate intravenously and phenobarbital by mouth, with no effect on the urticaria or vomiting. The urticaria gradually disappeared within a week, and the patient felt entirely well. Nine days after the onset of her reaction, 1,000 units of penicillin from the same lot as that previously used was administered. Two and one-half hours later urticarial lesions reappeared, but there was no nausea or vomiting. On the following morning, when the hives had disappeared, 3,000 units of penicillin were given. Six hours later, the patient observed the development of edema of the lips, but this reaction was not as severe as that following the previous injection of 1,000 units. The lesions cleared up promptly. Further penicillin therapy was not attempted. Skin tests, using 0.1 cc. isotonic sodium chloride solution containing 1,000 units, were performed. Penicillin of the same lot as that used previously on the patient produced erythema 0.5 cm. in diameter in thirty minutes; that from another lot produced erythema 4.0 cm. in diameter, and no reaction resulted from tests with two other lots of penicillin. Intradermal injection of human serum containing 0.1 unit of penicillin per cubic centimeter from a patient receiving penicillin produced no reaction. All twenty-four hour readings were negative.

An urticarial reaction to penicillin therapy may be severe, may be accompanied by asthma, may respond only moderately to Benadryl or Pyribenzamine therapy and may be followed by ecchymoses and uterine bleeding of undetermined cause.

Case 5.—M. D., a white woman physician aged 31, was first seen at the request of Dr. I. S. Ravdin on April 7, 1946 by Dr. Malcolm Spencer and one of us (D. M. P.) because of severe urticaria, laryngeal edema and asthma developing during prophylactic penicillin therapy following an operation on the left knee. The course of the patient's illness was severe and alarming and the cause of a subsequent hemorrhagic reaction was obscure; the history and clinical course are therefore recorded herewith in some detail.

The patient had been in generally good health, except that at the age of 16 she had undergone a dilatation and curettage because of dysmenorrhea associated with excessive uterine bleeding. This procedure was repeated in August 1945 because of similar symptoms. Sections of the endometrium taken on both occasions were reported to be normal on histologic examination. Further pertinent details may be outlined in chronologic order, as follows:

September 1945. Angioneurotic edema of the perioral region developed following the taking of a total of 360,000 units of penicillin by mouth during a period of three days, because of an infection of the upper part of the respiratory tract associated with diarrhea. The angioneurotic edema disappeared promptly on cessation of penicillin therapy.

March 8, 1946. The patient sustained a fracture of the medial semilunar cartilage in an automobile accident.

March 29, 1946. A medial meniscectomy of the left knee was performed. Prophylactic penicillin therapy in the amount of 30,000 units every three hours, intramuscularly, was started.

April 7, 1946. After eight days of satisfactory progress, there developed in the patient severe generalized urticaria, with several paroxysms of asthma. Penicillin therapy was suspended, and the patient was started on Benadryl in a dosage of 100 mg. three times a day.

April 8 and 9, 1946. The patient continued to have urticaria, laryngeal edema and asthma, for which a number of injections of epinephrine were required for relief.

April 10, 1946. Benadryl was adjudged to have been ineffective, and treatment with Pyribenzamine, 100 mg. by mouth three times a day was started. There was possibly some improvement in the urticaria, but the patient continued to have asthmatic attacks between 10 p. m. and 3 a. m.

April 11, 1946. The dosage of Pyribenzamine was increased to 50 mg. every four hours, around the clock. The asthmatic attacks disappeared, but occasional hives persisted.

April 12, 1946. The dosage of Pyribenzamine was increased to 75 mg. every four hours.. The urticaria remained troublesome, and on April 13 the dose was increased to 100 mg. every four hours. Complete freedom from asthma and urticaria occurred. There were no apparent untoward side effects from Pyribenzamine.

April 14, 1946. Because of shortage in the supply of Pyribenzamine, the dosage was reduced to 50 mg. every four hours. Urticaria shortly recurred. On April 15 the dosage was increased to 75 mg. every four hours, and this apparently relieved the urticaria. The patient was discharged from the hospital.

April 17, 1946. The dosage of Pyribenzamine was reduced to 50 mg. every four hours, and urticaria recurred.

April 18, 1946. Benadryl, 10 mg. in 20 cc. isotonic sodium chloride solution, was administered intravenously. Urticarial lesions disappeared almost immediately, and the patient slept for ninety minutes.

April 19, 1946. The patient resumed Pyribenzamine therapy, 100 mg. every four hours. The dose was then gradually reduced, and on April 23 Pyribenzamine was discontinued entirely, although occasional small hives were still being noted.

Benadryl and Pyribenzamine in the Treatment of Urticaria Due to Penicillin

	Total Cases Treated	Relief with Dose of 50-100 Mg. Three Times a Day	No Relief
With benadryl	16	14	2*
With pyribenzamine	7	2	5

* These patients received one dose of 10 mg. of benadryl intravenously, with temporary relief.

April 24, 1946. While visiting her home in another city, the patient noted vaginal bleeding which required three to four pads in twenty-four hours. The last previous menstrual period had started on April 10. The vaginal bleeding continued and on April 26 the patient also noted tarry stools, coffee-brown vomitus, epistaxis, gross hematuria, generalized ecchymoses and bleeding from the gums. On the following day the patient was seen by her home physician; the bleeding time was fourteen minutes, the hemoglobin content was 58 Gm. per hundred cubic centimeters and there were 13,700 white blood cells with 90 per cent polymorphonuclear leukocytes. Five hundred cc. of whole blood was administered. The bleeding gradually diminished. The patient was also given vitamin K, 5 mg. three times a day, intramuscularly and ascorbic acid 100 mg. twice a day intravenously. On April 30 a bleeding time of four minutes and hemoglobin level of 70 Gm. per hundred cubic centimeters was reported.

May 1, 1946. The patient was again seen by us and studied by Dr. Adolph Creskoff of the hematology department. At that time the hematologic findings were normal.

On May 3 the patient again noted profuse vaginal bleeding, had one bout of hematemesis, epistaxis and one tarry stool. It became necessary to pack the uterus and to administer three transfusions of 500 cc. of whole blood each between this date and May 8. When last seen May 25, 1946, the patient had apparently recovered entirely.

COMMENT

The etiology of this patient's bleeding is not clear, but it would seem that it was definitely related either to her reaction to penicillin or to the drugs used to combat this reaction. Proof of the cause of the bleeding could have been determined only by the experimental administration of penicillin, Benadryl and Pyribenzamine, but such a procedure was not considered justifiable in view of the severity of the reaction which the patient had experienced.

The overall experience with Benadryl and Pyribenzamine in the treatment of urticaria due to penicillin is summarized in the accompanying table.

SUMMARY

Urticarial and other allergic reactions to penicillin at times constitute a serious bar to continuance of treatment with this compound. It is to be expected that as more persons receive repeated courses of penicillin a higher incidence of reactions will be observed. This, in our opinion, is another of the several reasons for the use of penicillin only on adequate medical indications.

The prognosis in any particular urticarial reaction to penicillin in regard to both the duration of the attack and the likelihood of its recurrence on readministration of penicillin is difficult to make. The antihistamine drugs, Benadryl and Pyribenzamine, are often of great value in the control of urticaria due to penicillin, and it is sometimes possible to continue the administration of penicillin by the simultaneous administration of one of them.

On the basis of general principles applicable to allergic reactions to drugs and of our experience with urticaria due to penicillin, the following scheme of management of such reactions is suggested:

1. Stop the administration of penicillin immediately, except possibly in occasional instances in which there is an immediate critical need on the part of the patient for the drug.

2. Administer Benadryl or Pyribenzamine in a dosage of 50 to 100 mg. three times a day by mouth to adult patients. The effectiveness or lack of effectiveness of such treatment will ordinarily become apparent within twelve hours. It may be necessary to administer the antihistamine compound as frequently as every four hours, around the clock. If the reaction to penicillin is severe or if it is desired to attempt its administration without interruption, the intravenous administration of Benadryl in a dosage of 5 to 10 mg. given slowly in 20 cc. isotonic sodium chloride solution is advised. The hypnotic effect of its intravenous administration is often decidedly startling, and we are not convinced that it does not possibly have some dangerous potentialities.

3. If the urticaria and accompanying symptoms subside, a test dose of 1,000 units of another manufacturer's penicillin may be administered intramuscularly, provided that facilities for the administration of epinephrine or of Benadryl intravenously are at hand. It is recommended that administration of an antihistamine drug by mouth be continued during this period.

4. If there is no reaction to the test dose within six hours, another dose of between 10,000 and 20,000 units may be given. Provided no reaction is evident within four hours, the administration of penicillin may be resumed in full therapeutic doses, with continued administration of the antihistamine compound.

5. The dosage of Benadryl or Pyribenzamine may be reduced gradually over the next two or three days. If the urticarial reaction recurs, the dose of antihistamine drug should be increased to the level previously found effective. However, in some patients it will be possible to discontinue such drugs entirely while continuing the administration of penicillin.

6. During the period of trial administration of penicillin, the use of compounds which delay the absorption of penicillin and maintain the level of penicillin in the serum for prolonged periods of time, e. g. penicillin in peanut oil and beeswax, is not advised. Penicillin in a form which will be rapidly excreted, should a reaction occur, is preferable.

7. Should readministration of penicillin be found impossible and should further penicillin therapy be considered highly advisable, as in syphilis, for instance, another attempt at readministration one or more months later may be successful. It is obvious that this should be carried out cautiously, with the patient under close observation.

8. The prospective wider availability of crystalline penicillin fractions and of improved antihistamine compounds should shortly make the knowledge of the etiology of reactions to penicillin more exact and the means of preventing and treating them more effective. The problem is one of increasing importance and deserves careful study by laboratory and clinical scientists and by manufacturers of penicillin.

THE PROBLEM OF VENOUS THROMBOSIS

THOMAS B. AYCOCK, M.D.
and
JAMES W. HENDRICK, M.D.
Baltimore

Of all complications relative to surgical operation, delivery or illness requiring medical management, venous thrombosis which results in permanently disabling venous obstruction or fatal pulmonary embolism stands as the most distressing.

It has only been within the past few years that the problem of venous thrombosis has been understood. Homans [1] and Ochsner and DeBakey [2] have divided intravascular clotting into two types: (1) a bland thrombosis or phlebothrombosis and (2) thrombophlebitis. With this division a more rational method of management may be instituted.

Because of a number of factors [3] the condition of intravascular clotting is apparently on the increase. The greater number of operative interventions that are now being performed and the increase in the magnitude of present day surgical practice are the most logical reasons. This view has been stressed by Matas.[4] It was formerly thought that this condition developed only in patients who had undergone surgical intervention, but the work of Burke [5] and others [6] has shown that it occurs almost as frequently in patients receiving medical treatment.

From the Department of Surgery, University of Maryland School of Medicine and College of Physicians and Surgeons.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

ETIOLOGY

There are numerous factors which contribute to the development of venous thrombosis. Faure[7] found a greater instance during the winter months, especially when grippal infections were most prevalent. Also, more cases have been reported in Northern states than in Southern states. This fact could be attributed to the greater incidence of the infections of the upper part of the respiratory tract in the northern section of the country. Burke[5] emphasized a familial or constitutional tendency, and he noted the occurrence more frequently in asthenic, adipose types and in those persons who are hypothyroidic, overweight or weak muscled. Trosseau[8] noted the frequency of venous thrombosis that developed in patients with wasting diseases such as tuberculosis and especially cancer.

There are many plausible theories as to the development of venous thrombosis. The theory suggested by Frykholm[9] seems to have special merit: that when a patient lies in bed for some period of time the veins of the lower extremities are collapsed by the pressure of the leg against the mattress, with the result that the endothelial cells lining the venous wall may adhere to one another. The injured cells may become defective, roughened or torn loose, or thrombocytes and leukocytes may adhere to them; in either case these cells will act as a nidus for a thrombus. If this happens in a small vessel, it may easily be occluded. It is known that the leukocytes follow along the wall of the vessel, whereas the red blood cells are usually arranged in the middle of the stream.

Ochsner[10] suggested that vasospasm retards the flow of the blood in the lower extremities. The vasospasm may be due to the use of tobacco or to trauma such as that seen in fractures in which the vessel wall or surrounding tissues are injured. Circulatory retardation may be produced by posture, such as Fowler's position after abdominal surgery, in which the thighs are partially flexed on the abdomen and the legs on the thighs, causing a pooling of the blood in the popliteal veins. Immobility of the diaphragm caused by tight strapping of the abdomen after an abdominal operation and an increase in abdominal tension produced by intestinal gases may be factors. Ochsner and DeBakey[11] have also shown that after a surgical operation there are changes in the constitution of the blood which may be important in the occurrence of venous thrombosis. The changes in the plasma are an increase in its viscosity, hyperglobulinemia, hypoproteinemia and an increase in the fibrogen and calcium content. There are also changes in the formed elements of the blood, which consist of an increase in the number of thrombocytes and leukocytes and in their tendency to agglutinate.

Intravascular clotting is more frequently encountered in advancing age, as was shown by Allen and his co-workers,[12] who stated that 81 per cent of their cases were in patients over 40 years of age.

Barker and Priestley[13] of the Mayo Clinic in a review of 1,665 consecutive cases of postoperative venous thrombosis, pulmonary embolism and thrombophlebitis found that these complications occurred after 0.96 per cent of all operations and 2 per cent of all laparotomies and that this figure was increased to 3 per cent if the surgical procedure was performed on the female pelvis. It was further shown by these authors that patients with the following conditions were more prone to have these complications: carcinoma, disease of the peripheral veins, serious infections, cardiac diseases and hematic dyscrasias. These men stress the fact that patients with such conditions should have all precautionary measures instituted to prevent these complications when surgical intervention is contemplated.

In the opinion of most authorities[11] the site of the thrombus in phlebothrombosis is in the plantar veins or the veins of the calf muscles. In this case there is little or no inflammatory change in the vessel wall or in the vascular endothelium, but because of stasis and other factors previously mentioned there occurs the formation of a thrombus, which is similar to an extravascular clot in that it has a red color due to the presence of a high percentage of erythrocytes. Since the wall of the vessel is not involved the thrombus, which is exceedingly fragile, can easily become detached, especially when it gradually builds up and the end projects into a larger vessel. It is such a condition as this which frequently produces fatal pulmonary embolism when a patient first gets out of bed after an operation.

In thrombophlebitis there are maximum changes in the vessel wall which are produced by trauma to the wall, infection or, as Karsner[15] and Homans[16] have indicated, a perivenous lymphangitis. The deep portion of the femoral iliac system is the most frequently involved. Aschoff[17] considers that there is a deposition and agglutination of platelets on the injured vessel wall. Leukocytes and fibrin are also attached, producing a firm thrombus that is adherent to the wall. Such a thrombus as this is not so likely to become dislodged and produce pulmonary embolism.

CLINICAL MANIFESTATIONS

It is imperative that if adequate treatment is to be instituted, the clinical manifestations of each type of venous thrombosis be understood.

Phlebothrombosis.—As has been mentioned previously, a thrombus as a rule develops in the plantar veins or the veins of the calf muscles. From there it will extend into the popliteal and deep veins of the thighs and pelvis. At first there may be little or no evidence of involvement of the extremity. There may be only tenderness of the plantar surface of the foot or around the external malleolus or over the calf muscles. Veal and Hussey[18] stressed a localized tenderness over the veins of the lower part of the leg. Dorsal flexion of the foot with the leg extended (Homan's sign) was positive in a large percentage of patients in the University Hospital. An increase in the pulse rate is also a common observation. There may be no elevation of any importance in the temperature, unless it is produced by some concurrent condition. However, Allen, Linton and Donaldson [19] have stated that when a patient's chart shows a rise in the pulse rate, temperature and respiratory rate, it is strongly indicative of phlebothrombosis with a pulmonary embolism (figs. 1 and 2). The patient is often extremely nervous; he has an anxious look of impending danger. Edema of the foot and leg is seen in about 60 per cent of such cases, and when it is present postoperatively the patients should be carefully examined for indications of phlebothrombosis.

Sudden, sharp pain in the chest as a result of a pulmonary embolism was the first indication of phlebothrombosis in 41 per cent of patients in a series studied by Allen and his co-workers.[19] If the emboli are small, they may produce only pleuritis or substernal pain, faintness, coughing or bloody sputum; if they are massive, they may result in sudden death (figs. 3 and 4). Veal and Hussey [18] have shown that there is no period of safety from pulmonary emboli for a patient at any time from one day to four months after their formation if phlebothrombosis is present.

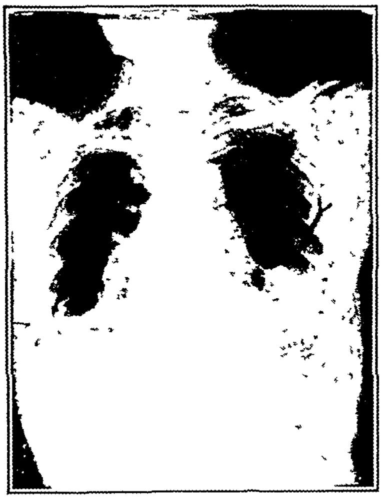

Fig. 1 —In a patient aged 68 with carcinoma of the prostate, the roentgenogram reveals a healing infarct at the base of the right lung and a recent infarct at the base of the left lung Bilateral superficial femoral ligation is present

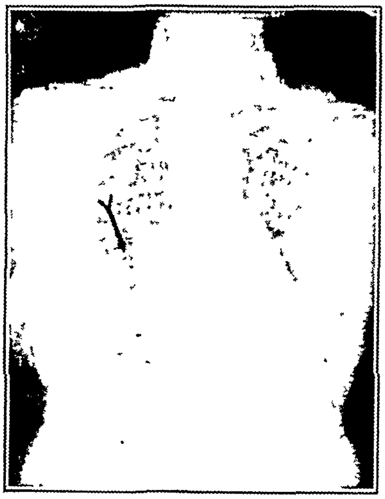

Fig 2 —In a patient aged 64, with rheumatic heart disease, the roentgenogram shows a pulmonary embolism at the base of the right lung.

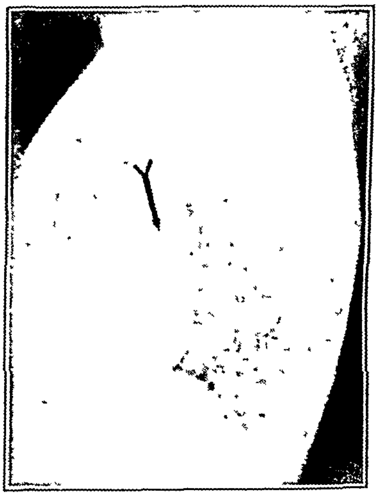

Fig 3 —Lateral view of patient in figure 2 shows triangular area of infiltration typical of pulmonary embolism.

Allen, Linton and Donaldson [19] found that the lower lobes of the lungs were involved more frequently than the upper; as a matter of fact, in 96 per cent of their cases this observation assisted in making a differential diagnosis (figs. 5 and 6).

There is no satisfactory method of determining when the process has propagated far enough to involve the femoral or iliac veins. However, Homans [16] has suggested that cyanosis of the extremity, especially when it is tender and when the collateral veins of the skin are disturbed, practically always means that the deep vascular system is involved. It is in such conditions as this that phlebography [20] may be of assistance.

Thrombophlebitis.—There is much discussion at this time whether thrombophlebitis begins in the femoral-iliac system and extends to involve the deep venous system or whether it begins in the plantar and calf-muscle veins and extends to involve the femoral-iliac system. According to Homans,[16] Ochsner and DeBakey [3] and Fine and Sears,[21] it is the full, obstructing type of thrombosis accompanied by a decided perivascular inflammation with swelling of the inguinal lymph nodes. Since there is involvement of the wall of the vein, there is less likelihood of the formation of pulmonary emboli. When they do occur they are, as a rule, of the septic type. The thigh and the extremity are usually noticeably swollen and edematous, and when the superficial veins are dilated the iliac system is also involved. In about 5 per cent of the cases the process involves the superficial system, in which event there may be little edema. Since there is an infection present, there is an accompanying rise in temperature and in the leukocyte count. If the temperature curve is of the picket-fence type associated with chills, a suppurative condition will be found to be present. Pulsation of the arteries of the involved extremity will be of poor quality. The edema, pain and poor arterial pulsations were shown by Leriche,[22] Ochsner and DeBakey [2] to be caused by vasospasm.

TREATMENT

Prophylaxis of Venous Thrombosis.—The best form of treatment for venous thrombosis is prevention. It was mentioned earlier in this paper that patients manifesting certain conditions were more prone to the development of this complication; it is not amiss to mention again these conditions and express the need for caution when they are present: carcinoma, disease of the peripheral veins, cardiac diseases, serious infections, hematic dyscrasias and trauma.

In the University Hospital the residents and nursing staff are taught to examine carefully the lower extremities of all surgical patients or medically ill older

patients twice a day, to palpate the plantar surfaces of their feet and their calf muscles and to note the presence of edema or dilatation of the superficial veins and the presence of pain in the muscles of the sole or calf. Any postoperative pain in the chest is immediately investigated to be sure that it is not the result of an embolism from a silent venous thrombosis. The surgical patients and the older age group of medical patients who are required to remain in bed are instructed to move their lower extremities as much as possible. As Wangenstein said, a thousand times a day is not too much. De Takats and Fowler[23] and Ochsner and DeBakey[3] have stressed dorsal flexion and plantar flexion of the feet. The patient is encouraged to breathe deeply; tight abdominal bindings are not permitted because they prevent deep breathing. Postoperative distention should be prevented; dehydration should be combated with an adequate intake of fluids; sufficient heat should be applied to the body to prevent chilliness, which may produce vasospasm and influence venous thrombosis.

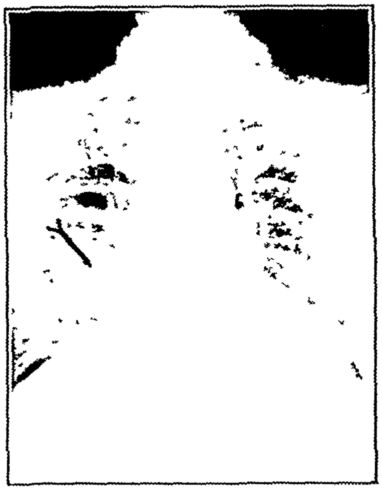

Fig 6—Roentgenogram of patient in figure 5 showing a pulmonary infarct in the lower lobe of the right lung.

Treatment of Phlebothrombosis.—When phlebothrombosis is present, or when a pulmonary embolus has developed from a silent thrombus, the most rational treatment is thrombectomy and ligation of the vein above the thrombus. This form of treatment was first used by Homans[1] and has been popularized by him and many others;[24] in fact, it is the accepted treatment for this serious condition.

Since the majority of thrombi have their origin in the veins of the feet or calf muscles, it is well to institute surgical treatment before the thrombus has propagated itself to involve the femoral or higher veins. By so doing the postoperative convalescence will be more satisfactory. Also, there will be less likelihood of the development of pulmonary emboli.

In early cases the site of ligation which we have found to be most advantageous is the superficial femoral below the profundi femoris. This site was popularized by Allen,[25] Linton and Donaldson.[10] In this area there are few muscle branches, the vein is readily accessible and there is a sufficient segment with which to work safely. Thrombi can easily be removed from the proximal and distal segments of the vein.

Operative Technic.—The technic which we employ operatively is essentially that which was advocated by Allen[10] and his co-workers[12] and Homans.[16] It is as follows:

Under local, Pentothal sodium or low spinal anesthesia a 4 inch (10 cm.) incision is made beginning below the crease of the groin and parallel to the pulsating femoral artery. The skin edges are carefully protected with towels. The incision is carried down to the vascular bundle; the femoral sheath is opened. The branches of the femoral nerve lie lateral to the femoral artery and vein. The femoral artery overlies the vein in this region. The artery is freed sufficiently, so it can be retracted laterally, and this is done gently. The superficial femoral vein now comes into view. If it is thrombosed it may adhere slightly to the femoral artery and surrounding tissues, in which event a higher ligation is done. The saphenous veins and venae profundae femoris should be identified. The superficial femoral vein is dissected out for a distance of about 3 cm. A strand of size 1 chromic catgut is placed under the proximal and distal ends and held with hemostats. The vein is incised transversely half through its diameter. Any clots which are present in the proximal or distal ends of the vein are removed with suction through a curved glass tube. Suction is then continued until free bleeding takes place from each end, if possible. However, it is more important that free bleeding develop from the proximal end. This may be encouraged by elevating the head of the operating table. After all clots have been removed the vein is ligated at each end and transected. A stitch suture of silk is also placed through each end of the vein. The wound is closed in layers in the usual manner.

If the superficial femoral vein is found to be thrombosed, the common femoral or the common iliac is exposed and ligated. It has been shown by numerous surgeons that it is unwise to ligate a diseased vessel wall, because clots in the proximal segment are difficult to remove or a thrombus may form again in the proximal segment and give rise to pulmonary emboli.

Also, because the vein wall is so fragile an uncontrollable hemorrhage could result.

Bilateral superficial femoral ligation is recommended, especially if pulmonary embolism has occurred, in which case thrombectomy is advocated. Postoperative edema has not been of any importance. Elastic bandages applied to the feet and legs can be worn from two to six weeks if edema of any consequence develops.

Dicumarol, 3,3′-methylene-bis-(4-hydroxycoumarin), has been used after superficial ligation with daily, careful estimates of the prothrombin time. We have found no ill effects from its use, except in transurethral resection and in disease of the thyroid and liver; however, it has been reported that others [26] have. As a rule, the patient is ready to be dismissed from the hospital five or six days after superficial femoral ligation if other conditions permit.

We have found also that bilateral vertebral block using procaine hydrochloride and monobromosaligenin (Bromsalizol, a product of Hynson, Westcott & Dunning, Inc.) is useful in giving a better circulation to the extremity the first few days after femoral ligation. Usually, only one block is necessary.

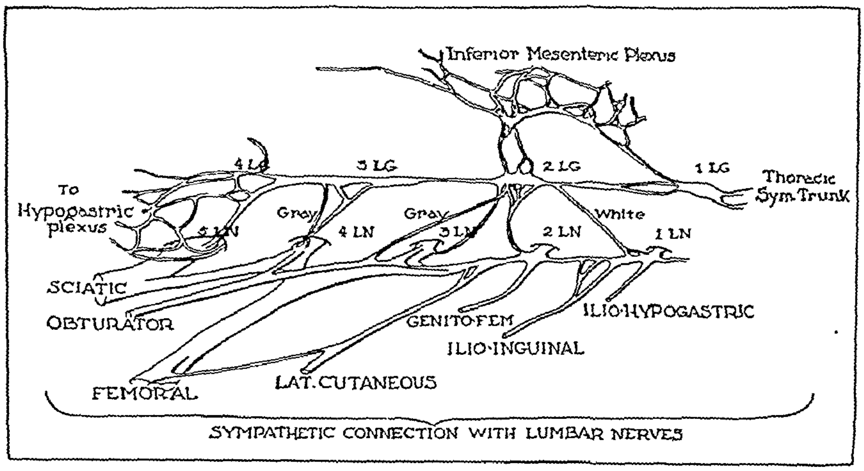

Fig. 7.—Anatomy of the lumbar sympathetic ganglions.

Case 1.—*Phlebothrombosis—pulmonary embolism.* Mrs. E. W., aged 71 years, entered the hospital March 1, 1946 with a Pott's fracture of the right ankle. The fracture was reduced, and a plaster of paris cast was applied. On March 6 the patient was put in a wheel chair, at which time she suddenly noted a pain in the left side of her chest. Faintness and symptoms of shock occurred. The temperature was 101 F., the pulse rate 120 and the respiratory rate 30. Her left leg was normal; tenderness was present over the femoral vein of the right leg. A bilateral superficial femoral ligation with right thrombectomy was performed. A long clot was removed from the right superficial femoral vein. The patient's convalescence was uneventful.

Case 2.—*Bilateral phlebothrombosis.* A. L., a white man aged 47, was first seen in the accident room. He stated that he had been walking more than usual for the past three days. The patient complained of pain on the plantar surfaces of his feet and in the calf muscles; a positive Homan's sign was present. Edema of his ankles was noticeable. The pulse rate was 100, the temperature 100 F.; the heart was normal and the blood pressure was 130 systolic and 80 diastolic. The patient seemed to have a feeling of impending danger. A diagnosis of bilateral phlebothrombosis was made. A bilateral superficial femoral ligation was performed under spinal anesthesia. Clots were removed from the distal end of each vein. The patient was discharged seven days later with no further trouble.

Case 3.—*Phlebothrombosis—pulmonary embolism.* W. S., a white man aged 50, entered the hospital Oct. 1, 1945 for repair of a right inguinal hernia. On October 11 the patient noted the sudden development of pain in the left side of his chest. The temperature was 100.8 F., the pulse rate was 110. A roentgen examination of the chest revealed normal conditions. Homan's sign was positive on the left leg. The left ankle showed slight edema. On October 16 a second attack of pain occurred in the lower left side of his chest and in the right popliteal area; there was a positive Homan's sign with edema of the right ankle. The pulse rate was 108, the temperature 101 F. and the respiratory rate 30. A diagnosis of bilateral phlebothrombosis with pulmonary embolism was made. Superficial femoral ligation and thrombectomy were performed. The patient's convalescence was uneventful.

Case 4.—*Bilateral phlebothrombosis—repeated pulmonary emboli.* Mrs. N. M., a white woman aged 44, was first admitted to the hospital July 1, 1945 with a history of repeated small pulmonary emboli. A diagnosis of left phlebothrombosis was made. A superficial femoral ligation was advised, but the patient refused to submit to the operative procedure. Her history and physical examination were not indicative of cardiac trouble, and she had not undergone previous surgical intervention. After treatment with Dicumarol the patient was discharged. On Oct. 9, 1945 the patient was readmitted to the hospital following a massive pulmonary embolism. A diagnosis of left phlebothrombosis was made; a positive Homans sign was present as well as edema of her left ankle. A *bilateral superficial femoral ligation* was performed with removal of clots from the distal ends of both veins. With the exception of the use of bandages for six weeks for treatment of edema of her ankles, the patient's convalescence was uneventful.

Treatment of Thrombophlebitis.—It was mentioned earlier in this discussion that there is little likelihood of pulmonary emboli developing in a patient with a well established thrombophlebitis. As Homans [16] wisely stated, the greater the swelling, the less danger of a soft detachable mass existing, and if embolism should occur, the veins of the other leg should be considered the offender. Previously the disability due to thrombophlebitis was relatively great; often the patients continued for the remainder of their lives with a swollen, tender leg that was prone to the development of trophic ulcers.

The most plausible theory in regard to the cause of the clinical manifestations in thrombophlebitis is vasospasm, as was suggested by Leriche.[22] Careful experimental and clinical work by Ochsner and DeBakey [2] has confirmed Leriche's observation. The vasospasm affects both the arterial and venous systems and in so doing disturbs the normal physiologic exchange of intravascular and perivascular fluids, thereby producing edema. When the vasospasm is relieved by sympathetic block of the regional sympathetic ganglion there is immediate improvement of the patient's condition. Within a few hours the pain disappears; the temperature rapidly returns to normal; good pulsations reappear in the dorsalis pedis and in the posterior tibial arteries. The skin, too, becomes soft as the edema begins to disappear.

When the lower extremity is involved, the first, second, third and fourth lumbar sympathetic ganglions are each blocked (fig. 7) with 10 cc. of a 1 per cent solution of procaine hydrochloride for the first to fourth ganglions and 10 cc. of monobromosaligenin each for the second and the third. The action of the procaine hydrochloride is immediate, and its effects will disappear within a number of hours. However, the action of the monobromosaligenin, while slower, will last from five to ten days.

---

[26] Barker, N. W.; Cromer, H. E.; Hurn, M., and Waugh, J. M.: The Use of Dicumarol in the Prevention of Postoperative Thrombosis and Embolism, Surgery *17:* 207-214 (Feb.) 1945.

When an upper extremity is involved, the most satisfactory method of treatment in our hands is the blocking of the first, second, third and fourth thoracic ganglions. Procaine hydrochloride alone is used. We[27] consider that monobromosaligenin[28] might be too irritating to the pleura. There have been no ill effects with the use of either of these solutions in a large series of cases of thrombophlebitis.

In addition to procaine blocking of the sympathetic ganglion the leg is elevated until the edema disappears, which usually occurs in from three to ten days. This is almost always true if treatment is instituted immediately after the condition develops. As the edema disappears active exercise is advised. If there is some persistence of the edema after the patient is allowed out of bed, an elastic stocking or bandage is worn for from two to six weeks. The bandage should incorporate the foot and leg up to and above the knee.

Case 5.—*Thrombophlebitis of the left leg.* P. S., a white man aged 28, was admitted to the hospital Sept. 6, 1945 after a fracture of the left humerus and multiple pelvis fractures. On September 24 thrombophlebitis developed in the left leg of the patient. His thigh was greatly swollen and was painful. Pulsations in the arteries of the left foot were of poor quality. The temperature was 103 F. and the pulse rate was 110. On September 25 a paravertebral lumbar block was performed on the left side. The first, second, third and fourth lumbar ganglions were each injected with 10 cc. of a 1 per cent solution of procaine hydrochloride. The second and third ganglions were each injected with 10 cc. of monobromosaligenin. On September 27 good pulsations were observed in the dorsalis pedis and posterior tibial arteries. There were less edema and pain at that time. On September 30 the leg and foot were practically normal. On October 1 a paravertebral block using procaine hydrochloride and monobromosaligenin was performed as before. On October 5 no residual signs or symptoms were present in the previously affected leg.

Case 6.—*Thrombophlebitis of the left leg.* Mrs. F. N., a white woman aged 64, was admitted to the hospital Aug. 8, 1945 with an inoperable carcinoma of the rectum. A permanent colostomy was performed, after which there developed a thrombophlebitis of the left leg. There was pronounced swelling of the foot, leg and thigh with poor pulsations in the arteries; the extremity was decidedly painful. The pulse rate was 112 and the temperature 103 F. A paravertebral lumbar block was performed, using procaine hydrochloride and monobromosaligenin in the same proportions as in case 5. This procedure was repeated in six days. After the first block the symptoms began to disappear; at the end of twelve days the extremity was symptom free.

Case 7.—*Thrombophlebitis of the left leg.* Mrs. M. S., a white woman aged 55, was sent to the hospital with nodular toxic goiter, with cardiac arrhythmia and a pelvic mass. Forty-eight hours after her admission to the hospital thrombophlebitis developed in her left lower extremity. The temperature was 102 F., the pulse rate 110 and the blood pressure 170 systolic and 100 diastolic. The extremity was decidedly swollen, edematous and painful. The pulsations in the dorsalis pedis and posterior tibial arteries were extremely poor. The left lumbar sympathetic ganglions were injected, as in cases 5 and 6. Ten days later the temperature and pulse rate were normal. The leg was soft and pulsations were normal, with but little edema remaining.

SUMMARY

Venous thrombosis is a frequent complication and is seen in both medical and surgical patients. It occurs more frequently in the older age group of patients.

Patients who have cancer, cardiac diseases, serious infections, disease of the peripheral veins, hematic dyscrasias and trauma are more prone to have this complication develop.

In phlebothrombosis, the thrombus most frequently develops first in the plantar veins and in those of the calf muscle and propagates itself into the deep veins of the thigh and pelvis. Pulmonary embolism is a frequent complication.

Thrombophlebitis completely occludes the vein and usually begins in the deep veins of the thigh and pelvis. Pulmonary emboli are infrequent, but a painful, edematous leg often results unless appropriate treatment is administered early.

Thrombectomy and ligation of the affected vein above the thrombus is the rational treatment for phlebothrombosis.

In thrombophlebitis blocking of the sympathetic ganglions with procaine hydrochloride and monobromosaligenin (Bromsalizol) effects a cure.

HEPARIN IN THE TREATMENT OF THROMBOEMBOLIC DISEASE

LEO LOEWE, M.D.
and
EDWARD HIRSCH, M.D.
Brooklyn

The purpose of this report is to present data regarding the rationale and effectiveness of heparin in the treatment of venous thromboembolic disease and to propose an improved method of heparinization, which is both safe and practical.

FUNCTIONAL PATHOLOGY

Although thromboses in the calf and plantar veins were observed for many years, the relationship between these minimal thromboses and fatal pulmonary emboli has been emphasized only in the past decade. It remained for Rössle,[1] Neumann[2] and Frykholm[3] to elaborate the anatomic development of pulmonary emboli and for Homans[4] and Bauer[5] to apply clinical and radiographic criteria by which aseptic deep calf thrombi could be recognized in their incipiency prior to the occurrence of pulmonary embolization. Based on the functional anatomy and clinical pathology of pulmonary embolization, Homans,[6] Bancroft,[7] Ochsner,[8]

Allen and his co-workers [9] and Bauer [10] then elaborated definitive principles of treatment for this condition.

It would be fitting at this point to trace the functional pathology of such a vascular accident. At the outset it must be admitted that many phases of the process are imperfectly understood and that many gaps exist in our knowledge of spontaneous intravascular clotting. Our interest in the genesis and nature of intravascular clots was stimulated during our investigation of experimental human frostbite.[11] A study of the train of events in this condition by Greene,[12] and Rotnes and Kreyberg [13] revealed that there is a clumping of erythrocytes in the dilated arterioles for at least seventy-two hours after exposure. This clumping has been attributed to loss of plasma through the highly permeable vascular wall. As a result the red cells are stranded, silting up the blood vessels and forming what may be called a sludge. A related and revealing circumstance may be witnessed in the work of Knisely, Eliot and Bloch [14] on the formation of sludge in the blood during malaria and in traumatic shock. They have observed that the red cells become agglutinated to each other and form small clumps, as a result of which the flow of blood becomes sluggish and generalized thromboses supervene.

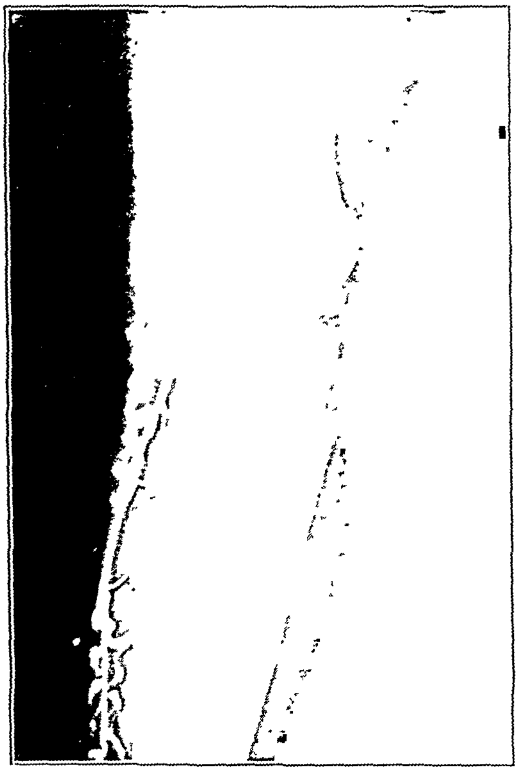

Fig 1—Phlebogram taken five months after femoral venous thrombosis treated by lumbar paravertebral block. Note the abnormal venous shunting through superficial channels and the failure of visualization of the deep venous system due to thrombotic occlusion of the femoral vein.

It is a well established fact that the blood platelet count rises rapidly in the immediate postoperative period, during which time the platelets become hyperadhesive.[15] Both phenomena attain their maximum peak about the tenth day after operative intervention. In addition to sludge formation and the changes in the number and quantities of platelets, the postoperative period is accompanied by a variable hemoconcentration, increased viscosity of plasma, hyperglobulinemia and increased fibrinogen content. Since all these factors contribute to clot formation, the stage is set for intravascular thrombosis anywhere in the body.

Although all the component elements for clot formation are present, we are still unaware of the precise catalyzing circumstance which initiates the chain reaction. In a statistical review of phlebothrombosis, one suggestive fact emerges, that a common denominator may be the slowing of the venous vascular stream, whether because of acute angulation or actual obstruction or by increased venous pressure secondary to either obesity or cardiac insufficiency. If one considers what part of the body would be most subject to slowing of the blood stream, for self-evident reasons the lower extremities must rank first. Thus during the postoperative period, in the presence of these chemical and physical changes in the blood, minimal intimal trauma in a venule of the lower extremity may well initiate a local intravascular thrombosis.

The original thrombotic process usually starts in the smaller vessels in the muscular portions of the calf and, less frequently, in the plantar veins. The clot progresses and soon reaches a larger vessel, into which it extends and grows. The clot is at first attached only to the venule and only later engages the wall of the larger vessel. As the clot propagates it consists in the main of the red cell clot which waves freely in the vascular stream. This clot contains minute amounts of fibrin and is but one stage removed from the sludges observed in experimental frostbite and in malaria.

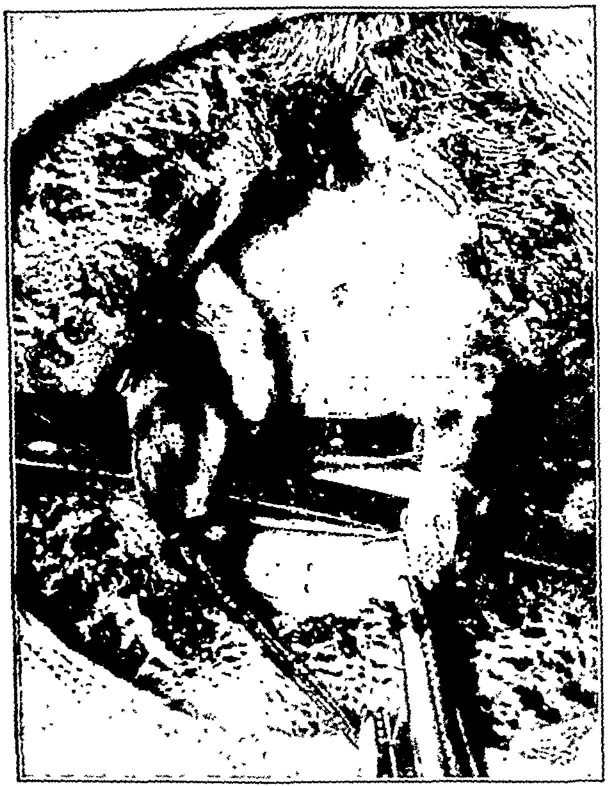

Fig. 3.—Nonheparinized control: jugular vein of a rabbit six days after trauma, presenting a visible and palpable clot.

We have reproduced this intermediate stage in the laboratory—a palpable, visible clot, which, however, is so loosely put together that it disintegrates readily. As the clot grows, the propagating proximal end represents all the stages previously described. It is now that the clot is most dangerous, for it may separate at any time, either spontaneously or as the result of some muscular exertion, such as straining at stool or getting out of bed. If the clot does not become detached it slowly becomes organized, attaching itself to the vessel wall during the process. During the stage of clot propagation immediately adjacent tributaries and collateral vessels are also involved; consequently, when organization with either obliteration or recanalization occurs there is a shunting of the venous stream to superficial vessels incapable of bearing the burden. This bizarre venous shunting is readily seen in postthrombotic phlebograms (fig. 1). Although we have been discussing so-called aseptic phlebothrombosis, essentially the same process occurs in the infective thrombophlebitis, in which the most proximal portion of the clot resembles the noninfective variety.

In either the aseptic or septic types of thrombophlebitis, if the process continues long enough, a periphlebitis occurs which involves the adjacent perivenous lymphatics. Lymphatic fluid is capable of coagulating, and it is quite conceivable that postphlebitic edema may be due in great part to consequent obstruction of the return lymphatic flow of an extremity.

RATIONALE

It is obvious that, in the situations which we have described, termination of the progressive thrombotic process would be ideal. To the best of our present knowledge the anticoagulants appear most suited for this purpose. Of these, we have been impressed by the properties of heparin. The accepted knowledge concerning the mechanism of action of this agent is as follows: (1) it prevents, with the aid of a plasma cofactor, the conversion of prothrombin to thrombin; (2) it forms a strong antithrombin in conjunction with serum albumin, and (3) it prevents the formation of thromboplastin from platelets. These properties predicate the fact that a clot, regardless of what stage it is in, cannot propagate in the presence of heparin. However, what happens to the clot which is already present?

The action of heparin has been studied mostly in vitro. Animal experiments in our laboratory[16] have yielded the following data:

1. Red cell clots which are not organized and which contain a minute amount of fibrin (sludge stage) disappear completely under heparin therapy (figs. 2, 3, 4, 5 and 6).

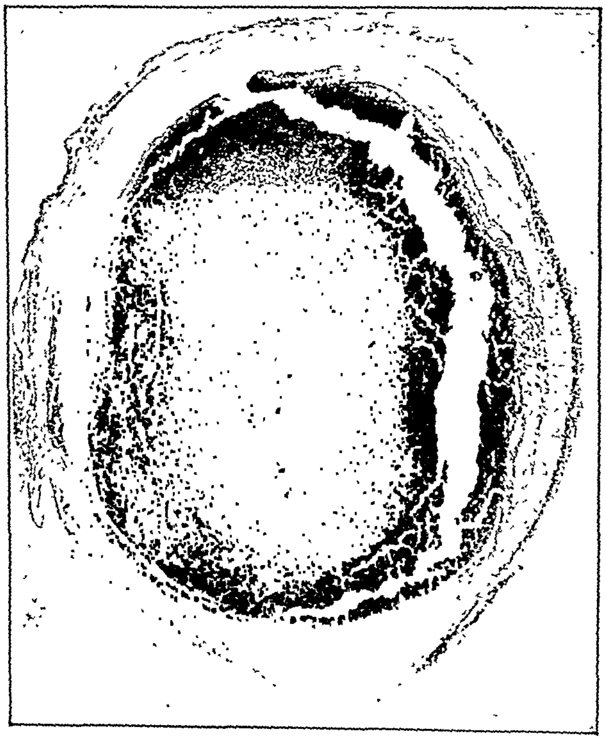

Fig. 4.—Photomicrograph of section of jugular vein (fig. 3) with all coats intact. The blood presents no classic evidence of clot and is present as particulate masses with a minimum of fibrin (sludge); magnification slightly reduced from × 30.

---

[16] Our method of consistently producing clots in rabbits has been to traumatize the jugular vein with twenty hammer strokes after it has been ligated proximally. This work will be fully reported in a forthcoming paper.

2. Heparin therapy maintains patent adjacent collaterals and tributaries, which ordinarily would become involved in the thrombotic occlusive process. These compensatory collaterals often become as large as the originally occluded vessel (fig. 7). This phenomenon has not been observed in control animals (fig. 8). It may be assumed, though not necessarily proved, that these processes also occur in obstructed lymphatic vessels.

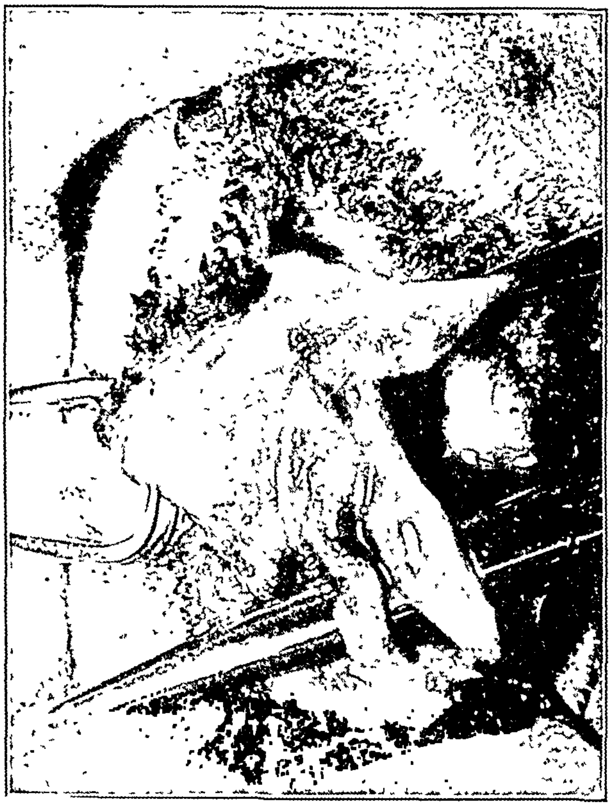

Fig 5.—Jugular vein of rabbit six days after trauma with fourteen days of heparinization superadded. The wall is thickened, but no gross evidence of clot is visible. Compare with the control nonheparinized vein (fig. 3).

Although methods of treatment of thrombophlebitis are legion, two major thoughts have dominated the clinical scene during the past five years; namely, the ligation of veins and anticoagulant therapy. The ligation of veins need not be discussed here, since the literature abounds in articles advocating this form of therapy. Our contrary views on the matter have been set forth elsewhere.[17] We do *not* believe that bilateral vein ligation as recommended can be classified as an innocuous procedure.

Anticoagulant therapy deals with the abnormal physiology of blood and lymph everywhere in the body. Dicumarol and heparin have been the most widely used anticoagulants. Delayed action, potential hazards and the requisite complicated but indispensable laboratory procedures militate against Dicumarol as the anticoagulant of choice. The action of heparin on the other hand is prompt and readily controlled and administered. Heretofore, the major drawbacks to the administration of heparin have been the necessity of maintaining adequate anticoagulant levels by a continuous intravenous drip method with its accompanying discomforts and inconveniences to the patient and physician alike and the inordinate quantity of the drug required, with its attendant expense.

These objections have been overcome by incorporating the drug in the Pitkin menstruum,[18] which was developed to retard the rate of release of water-soluble drugs injected subcutaneously or intramuscularly.

Heparin/Pitkin menstruum is a preparation of various amounts of heparin with or without vasoconstrictor drugs dissolved in the Pitkin menstruum, which is composed of gelatin, dextrose and glacial acetic acid in definite proportions which vary according to the amount of heparin. The various formulas[19] (table 1) were devised so that the dosage might be varied as indicated in the treatment of the individual patient.

TABLE 1.—*Heparin/Pitkin Menstruum Formulas*

	With Vaso-constrictors		Without Vaso-constrictors	
Crystalline sodium salt of heparin, mg.	300.0	200.0	800.0	200.0
Epinephrine hydrochloride, mg.	1.0	1.0	0	0
Ephedrine sulfate, mg.	25.0	25.0	0	0
Chlorobutanol, mg.	0.5	0.5	0.5	0.5
Eucupin * dihydrochloride, mg.	1.0	1.0	1.0	1.0
Pitkin menstruum, cc.	3.0	2.0	8.0	2.0

* Contains 1 per cent eucupin base, 3 per cent ethylaminobenzoate and 5 per cent benzyl alcohol in oil of sweet almond.

In general the anticoagulant action of heparin in the menstruum combined with vasoconstrictor drugs is more prolonged than that of the same amount of heparin in the menstruum without the vasoconstrictor

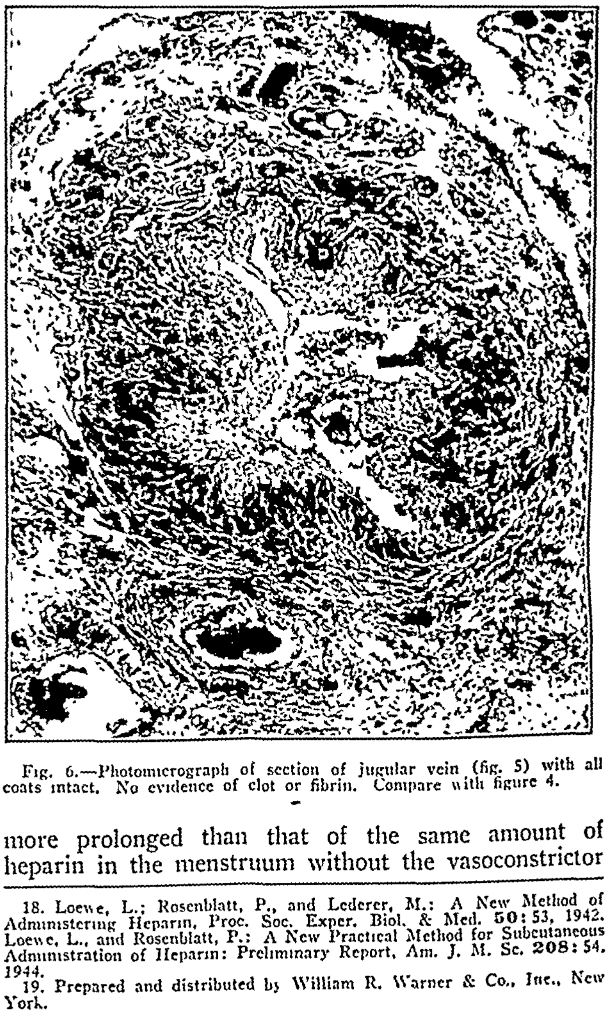

Fig. 6.—Photomicrograph of section of jugular vein (fig. 5) with all coats intact. No evidence of clot or fibrin. Compare with figure 4.

drugs. In thromboembolic venous disease heparin with vasoconstrictor drugs is customarily employed.

Heparin/Pitkin menstruum given as a simple deep subcutaneous deposit every two or three days supplants the technically more difficult intravenous administration of the aqueous solution. Thus, the total requirement of heparin for a given patient is greatly curtailed, and the overall cost of the treatment program is materially reduced.

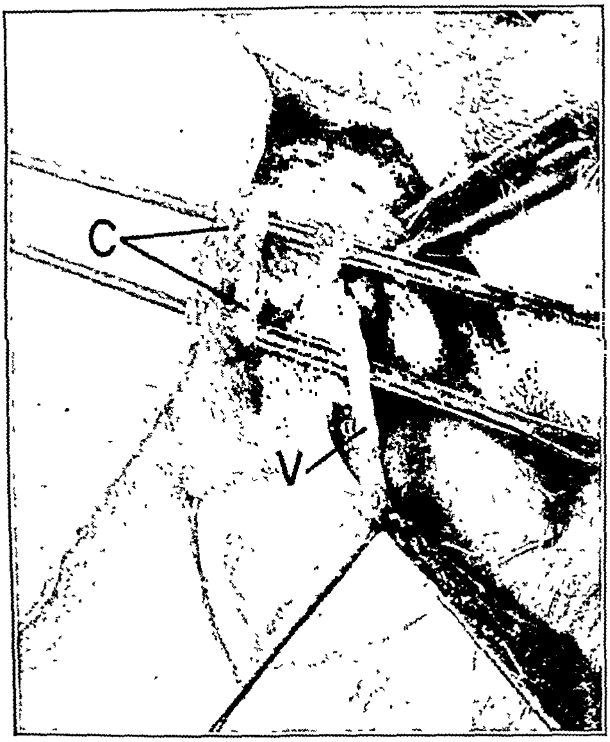

Fig. 7.—Jugular vein of rabbit fourteen days after trauma with fourteen days of heparinization superadded. Minimal, if any, blood flow through the traumatized vessels (*V*). Note the dilated extensive compensatory collaterals (*C*). Compare with the control nonheparinized vein (fig. 8).

The technic of administration of heparin in the Pitkin menstruum, its clinical use and the method of following the patient's clinical course has already been presented in great detail in previous communications.[20] The one objection to the preparation, the pain factor so disturbing to the patient, has now been overcome by careful buffering which has made the p_H of the gel more physiologically acceptable.

CLINICAL OBSERVATIONS

The clinical deportment of heparin in the Pitkin menstruum has been observed in 168 patients[21] representative of all forms of venous thromboembolic disease (table 2). The results continue to be eminently satisfactory as judged by the effective control of pulmonary embolization, the prompt amelioration of pain and discomfort, the rapid recession of edema, the reduction in morbidity, the acceleration of convalescence and the virtual absence of residual edema, particularly when patients are treated without delay.

Most informative are the statistics with respect to the patients who had pulmonary embolization. There were 4 fatalities in this group, representing over 2 per cent of the entire series of 168 patients and over 6 per cent of the 63 patients who had suffered from one to six episodes of pulmonary embolization. These 4 treatment failures occurred early in our experience, before the optimum treatment program had been established.

The span of treatment for uncomplicated thrombophlebitis and/or phlebothrombosis is ten days to two weeks. For patients with pulmonary embolization an additional week or two of therapy is required, depending on the extent of pulmonary infarction. In any event the full effect of heparin must be present at the time when the patient is first allowed out of bed. The consistently favorable response has fully justified our conservative plan of therapy.

Table 2.—*Heparin Treatment* of One Hundred and Sixty-Eight Consecutive Patients with Venous Thromboembolic Disease*

Classification	No. of Patients	No. of Patients with Pulmonary Embolization	Deaths Due to Pulmonary Embolization
Postoperative thrombophlebitis and/or phlebothrombosis	75	31	3
Thrombophlebitis and/or phlebothrombosis, miscellaneous †	51	23	0
Postpartum thrombophlebitis	21	5	0
Postinfectious thrombophlebitis	9	0	0
Post-traumatic thrombophlebitis	7	4	1
Migrating thrombophlebitis	5	0	0
Totals	168	63	4 (2.4%)‡

* Administered in Pitkin menstruum as a deep subcutaneous deposit.

† Occurring without ascertainable exciting cause (thrombophiles) or as a complication of carcinoma or varicose veins.

‡ Four treatment failures, 2.4 per cent of entire series and 6.3 per cent of 63 patients with pulmonary embolization, occurred before the optimum treatment program was established.

[20] Footnotes 17 and 18.

[21] This series of cases was recruited principally from the Departments of Surgery, Medicine, Gynecology and Obstetrics of the Jewish Hospital. We wish to thank them for referring this clinical material.

Papaverine is used concomitantly in liberal dosage; 1 to 1½ grains (0.06 to 0.09 Gm.) every four hours intramuscularly or intravenously, then, later, maintenance dosages by mouth. The use of digitalis is discouraged because of its possible thromboplastic influence, and smoking is strictly forbidden. Paravertebral block, although optional and effective in arterial occlusion, is not incorporated in the treatment program for venous thromboembolic disease, since we have observed that the complicating vasospasm in this disorder disappears almost immediately after the conjoint use of the subcutaneous heparin/Pitkin menstruum and papaverine.

Although truly comparative statistics are still not available, a review of our clinical material considered in the light of our animal experimentation continues to make subcutaneous heparin, which has supplanted ligation of the proximal veins in our clinic, the treatment of choice in venous thromboembolic disease.

SUMMARY AND CONCLUSIONS

1. The functional pathology of intravascular clotting has been outlined as a basis for evaluating the treatment of thromboembolic disease.
2. Heparin plays a vital role in arresting the progress of intravascular thrombosis and promotes restoration of the vascular stream.
3. Heparin in the Pitkin menstruum was employed in the treatment of 168 consecutive patients with venous thromboembolic disease with satisfactory results.

VENOUS THROMBOSIS AND PULMONARY EMBOLISM

ARTHUR W. ALLEN, M.D.
ROBERT R. LINTON, M.D.
and
GORDON A. DONALDSON, M.D.
Boston

This communication will present the experience at the Massachusetts General Hospital with thrombosis and embolism up to June 1946. Previous reports have stressed the importance of this syndrome and have called attention to the diagnostic criteria.[1] The safety of interruption of the femoral veins in the treatment of this disorder has been demonstrated. We wish now to record our present views on the subject including a controlled study on the use of Dicumarol.

PROPHYLAXIS

Prevention of thrombus formation in the deep veins of the legs is, in fact, the basic principle on which investigators in this field have been working for many decades. Progress has been slow, yet through a coordination of ideas much has been accomplished along these lines. Inasmuch as thrombosis within the veins is most apt to occur as a complication of illness or operative intervention, the opportunity for prophylaxis against this additional hazard to the patient is often overlooked or for obvious reasons is not easily carried out. Trauma to and stasis in the veins may be avoided in many instances, but often the actual disease or injury precludes certain forms of prophylactic treatment which have been found useful under more suitable conditions. It is our belief that various types of patients can be protected against embolism by utilizing the forms of preventive measures best suited to the particular case.

In the first place, we must face the facts concerning the frequency and seriousness of thrombosis and embolism with reference to the age and general condition of the patient. Our records show that these complications are much less likely to develop in the young than in the aged. Also, the more debilitated the patient, with added restrictions as regards mobility of the extremities plus trauma and infection, the more likely it is that thrombosis will occur. That all forms of prophylaxis are not adaptable to all patients seems obvious; yet many reports on the subject imply that one method may be applied regardless of the age factor and often without regard to the disease or injury under treatment.

Dicumarol can be safely used in a considerable number of patients. As shown by our comparative data, it is effective in the prevention of thrombosis and embolism even with the small dosage which we have tried. On the other hand, we have not considered it safe to use this drug in many patients for reasons shown in our table of contraindications (table 1). We have withheld it from the older age group on the basis of complications in the presence of arteriosclerosis after the use of heparin. Our reason for not using Dicumarol in the younger age group was primarily the infrequency of thrombosis and of fatal embolism in patients under 40 years of age. We admit that we could with safety give the drug to many of the younger patients and that we would use it as a part of the treatment of thrombosis and embolism in any event.

It seems to us that the age group between 40 and 65 is the correct one in which to use Dicumarol for the prevention of thrombosis. In this group there are many patients with serious ailments who are apt to be restricted in their activities by either their disease or the therapeutic measures indicated. In many of these patients, if left untreated, there will develop thrombosis of the veins of the legs, and many will have pulmonary emboli—some of which will be fatal. In those who recover the convalescence will be prolonged. Unless there is a contraindication to the use of Dicumarol, or unless laboratory control of the prothrombin time is not available, the majority of this group of patients can be protected from thrombosis and embolism by using small doses of this drug postoperatively.

In those patients beyond the age of 65 and in selected prematurely old or debilitated persons we believe that the best method of protection against thrombosis and embolism is interruption of the superficial femoral veins. It took considerable courage to adopt this point of view, but we were so impressed with the complete lack of circulatory or lymphatic disturbance after the interruption of the normal superficial femoral vein that we now have no hesitation in advocating this procedure as a method of choice (table 2). More instances of fatal embolism without warning occur in this older age group. We have no proof that phlebothrombosis is more likely to develop than thrombophlebitis. It

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

[1] Allen, A. W.; Linton, R. R., and Donaldson, G. A.: Thrombosis and Embolism, Ann. Surg. **118**: 728-740, 1943; Venous Thrombosis and Pulmonary Embolism, J. A. M. A. **128**: 397-403 (June 9) 1945. Allen, A. W.: Thrombosis and Embolism, Bull. New York Acad. Med. **22**: 169-184 (April) 1946.

appears, however, that a much higher percentage of the older patients have enough thrombus detach at one time to cause death than do the younger ones. True phlegmasia alba dolens, as it is seen in young convalescents, is much more infrequent in the aged. Since the bland type of thrombosis is so much more dangerous from the standpoint of embolism than is the inflammatory type, we have a further indication for vigorous prophylactic measures in the older group of patients.

In patients under the age of 40 we consider that there is less need for the routine use of interruption of the femoral veins or Dicumarol therapy as prophylactic measures against thrombosis, if the clinician keeps alert and institutes proper treatment when indications arise. It is helpful to carry out systematic active exercises of the legs and to avoid tight dressings and abdominal distention. Gravity to keep the leg veins empty and the use of pressure bandages on the legs are helpful adjuncts. In addition, one must carefully examine the legs twice a day for signs of swelling, dilatation of the superficial veins and tenderness along the course of the deep veins. Also, one must carefully evaluate any pain or discomfort in the legs as well as in the chest. The clinical chart is of importance, since the simultaneous recording of a slight elevation of temperature, pulse rate and respiratory rate gives a clue to phlebothrombosis, even when there are no signs in the legs or pain in the chest. Routine use of the drug in this age group would put a heavy strain on the laboratory, which would outweigh its advantages. Routine prophylactic interruption of the superficial veins, would put an unwarranted burden on the operating rooms.

Early ambulation has been used in our hospital for a number of years and has many advantages in approximately one half of the patients treated by surgical means. With wounds made on an anatomic basis and with the use of nonabsorbable sutures we can avoid some of the usual complications of convalescence. Patients do not get soft from long rest in bed and are able to return to their regular occupations at a much earlier date. Normal bodily functions are enhanced and many hospital days are saved. It was felt that early ambulation might lower the incidence of thrombosis and embolism. There is considerable evidence against this and little to support it.[2] Perhaps the chief factor in our disappointment in this regard is due to the misinterpretation of the term early ambulation. This should mean that the patient actually gets out of bed and walks and then lies down again. Instead of this, we find these patients sitting in a chair with their feet on the floor after having actually been lifted there from the bed by a well meaning orderly. Stasis in the leg veins, being increased by such a maneuver, may well offset any other beneficial effect that early rising may have. We now believe that, unless patients can carry out the muscular activity needed to keep the leg veins empty, early risers should be protected from thrombosis and embolism according to the principles outlined for the various age groups.

THERAPY

Treatment of thrombosis of the deep veins of the legs, with or without pulmonary infarct, has been under discussion from several points of view. In the first place, one must differentiate between phlebothrombosis and thrombophlebitis. In the bland type of thrombosis one has little opportunity for therapeutic measures that are effective other than interruption of the deep vein—preferably above the thrombus. The diagnosis is often made after infarct has taken place. Too often such a complication is unsuspected, and the patient may die suddenly from massive embolism when otherwise making a satisfactory recovery. In such patients there may be little to indicate the existence of thrombosis. On careful examination, however, there can usually be found sufficient evidence to warrant the institution of proper therapy. Unfortunately, such minor signs as dilatation of the superficial veins of the foot, slight swelling of the extremity or a concomitant slight rise in temperature, pulse rate and respiratory rate are often overlooked. Even sudden pain in the chest may be attributed to atelectasis, pleurisy or pneumonitis, when in fact infarct has occurred.

TABLE 1.—*Reasons for Contraindication of Dicumarol Therapy*

Reason	Percentage
Hospitalized for minor procedures	47.5
Admitted for study, no surgical operation	18.0
Disease of the liver	5.5
Hypertension	7.0
Disease requiring chest surgery	6.0
Plasma prothrombin determination above 25 seconds	6.5
Hyperthyroidism	3.5
Excessive bleeding at operation	2.5
Diabetes	2.0
Arthritic patients taking acetylsalicylic acid	1.5
Total	100.0

Of 985 patients between the ages of 40 and 65 who were admitted to the East Surgical Service of the Massachusetts General Hospital from Jan. 1, 1945 to June 1, 1946 Dicumarol was received by 162 (16.5 per cent). In the remaining 823 patients, use of the drug was contraindicated.

TABLE 2.—*Incidence of Therapeutic and Prophylactic Interruption of the Femoral Vein in 1,281 Cases from 1937 to June, 1946*

	Therapeutic	Prophylactic		Total
1937 to 1942	202	0	0%	202
1943	150	15	9%	165
1944	208	72	26%	280
1945	241	178	45%	392
1946 (June 1)	150	92	38%	242
Total	924	357		1,281

Thrombophlebitis is a term which should be used only when inflammation in and about the veins and lymphatics produces pain, swelling, tenderness and fever. This type of thrombosis may come on quickly, and in its fulminating form is known as phlegmasia alba dolens. If such is the case infarct is less apt to occur, and if it does it may not be massive in character. It is justifiable to treat patients with such types of thrombosis by procaine block of the lumbar sympathetic nerves,[3] elevation, the local application of heat and even activity. The anticoagulant drugs are valuable in the treatment of such conditions, inasmuch as they prevent spread of the thrombotic process. In this type of thrombosis interruption of the femoral veins is justifiable only in the early phases of the disease. Ligation of the vena cava is indicated if such a thrombosis is the cause of repeated septic infarcts.

Between phlebothrombosis and thrombophlebitis there are all gradations of the disease. In many patients thromboses which are apparently bland in the beginning will gradually develop into thrombophlebitis. This change in character may not be a real one, since the inflammatory element may be present in the beginning of a bland thrombus. The gradual, insidious onset as opposed to the sudden development of the fulminating inflammatory type of the disease may, in fact, be dependent on the virulence of the micro-organisms associated with the infection. That some cases of phlebothrombosis remain as such is certain. Most of the sudden fatalities from massive embolus occur while the thrombus is bland and not held firmly within the vein by inflammation. It has been obvious to us, in our climate at least, that in the majority of survivors from phlebothrombosis there develops a true inflammatory reaction in and about the involved veins if treated expectantly.

---

[2] Blodgett, J. B., and Beattie, E. J.: Early Postoperative Rising: A Statistical Study of Hospital Complications, Surg., Gynec. & Obst. **82:** 485-489 (April) 1946.

[3] Ochsner, A., and DeBakey, M.: Thrombophlebitis: Role of Vasospasm in the Production of Clinical Manifestations, J. A. M. A. **114:** 117-124 (Jan. 13) 1940.

Phlebotomy and thrombectomy with interruption of the superficial femoral veins not only prevents fatal embolism but shortens the course of thrombophlebitis. Most of our patients have this operation performed before any signs of inflammation are apparent, and in many of these thrombophlebitis fails to develop. In fact, many of them have venous interruption performed before the thrombus has reached the level of the common femoral vein. Some of them, however, do run a mild course of thrombophlebitis after the interruption of the femoral veins. A small percentage of patients continue to have infarcts after this operation. Patients who have pain, tenderness and swelling in the leg after interruption of the veins and those who continue to have infarcts are treated further by procaine block of the lumbar sympathetic ganglions and by anticoagulants.

The treatment of phlebothrombosis and early thrombophlebitis by anticoagulants alone has not recently been used in our clinic. Earlier experiences revealed that such management in our hands was unsatisfactory.[4] Some patients did well on heparin therapy as long as the drug was continued. However, it was found that the process flared again shortly after heparinization was stopped, and 1 such patient succumbed to massive embolus during this treatment. It therefore seems illogical to us to use this method of treatment against this disease unless it has been preceded by interruption of the femoral veins.

OPERATIVE TECHNIC

After observation of repeated instances of the lack of complete understanding in regard to our conception of the way and manner in which interruption of the femoral vein should be carried out, we feel justified in emphasizing the details of operative technic. The dangers of interruption of the common femoral and saphenous veins have been stressed by Dennis,[5] who reported an instance of fulminating edema subsequent to such a procedure. The patient's leg was saved by liberal incisions down through the fascia to the muscles. In addition to this danger we have pointed out the increased difficulties of exposure of this segment of vein, due to its short course and numerous muscular branches. Should one find that the vena profunda femoris is thrombosed at the time of interruption of the superficial femoral vein, the ligature can be placed around the profunda with greater ease than an interruption of the common femoral itself could be performed. This ligature adequately eliminates the vena profunda femoris as a source of subsequent emboli and, when combined with proper interruption of the superficial femoral vein, accomplishes the same result as does interruption of the common femoral vein.

In our opinion interruption of the iliac veins as advocated at one time by Homans[6] is not often indicated. This attack on the problem is theoretically sound, since the ligature can more often be placed around the vein above the thrombus. Practically, however, it has many disadvantages. Particularly hazardous is the necessity for two major operations, which must be performed under a form of anesthesia which is more dangerous than local infiltration on these exceedingly ill patients. It may be argued that only one iliac vein need be tied if the other is uninvolved. If both iliac veins should need interruption on the basis of septic thrombosis with repeated infarcts, it seems to us that ligature of the inferior vena cava is a better procedure. Our experience would indicate that such an operation is seldom necessary, since the results from phlebotomy and thrombectomy through the superficial femoral vein have proved to be satisfactory in such a large number of cases.

One of us (R. R. L.) has performed this operation on 13 patients. In this group it was not found necessary to interrupt the ovarian veins, but this added step should be considered, as has been pointed out by Collins and associates.[7] In 2 patients in this group there has developed chronic ulcer of the lower legs, and a third one has had a recurrence of ulcerations, which incidentally have responded to femoral vein interruption. These experiences have made us hesitate to interrupt the inferior vena cava except in the unusual and infrequent case of septic thrombosis with pulmonary infarction.

It is important that the lymphatic vessels in the region of operative intervention be interfered with as little as possible. This is one of the chief reasons for avoiding an incision that transects the lymph channels. Transverse or oblique wounds are certain to interrupt lymphatic vessels and should never be used to expose the deep femoral vessels. The most persistent and disabling edema that we have seen after interruption of the femoral veins occurred in a patient operated on in another hospital through a 6 inch (15 cm.) oblique incision below the crease of the groin. In spite of the natural lines of cleavage in the skin being transverse or oblique in this region, it is difficult when such an incision is used not to carry the dissection across many of the lymphatic vessels.

Another important disadvantage to the oblique or transverse incision is that it handicaps the surgeon in the exposure of the femoral vessels; if severe bleeding is encountered, due to the accidental tearing of one of the tributaries of the femoral vein, serious and irreparable damage may be done to the femoral artery in attempting to control the hemorrhage. One of us (R. R. L.) has recently been consulted in such a case at another hospital. The surgeon, using a transverse incision, encountered serious venous bleeding during the operation. Before it was controlled both the superficial and deep femoral arteries were ligated to save the patient's life from hemorrhage. The circulation of the extremity had been irreparably damaged when first seen, necessitating a low thigh amputation at a later date. The use of a vertical incision will prevent such catastrophes, since with it more complete exposure of the femoral vessels is obtained; and if accidental hemorrhage is encountered it can be more readily controlled, if necessary by further extension of the incision. The use of this type of incision is one of the cardinal principles in the surgery of major blood vessels of the extremities and it is our opinion that its use in interruptions of the femoral veins cannot be overemphasized.

An incision about 8 cm. in length from the crease of the groin over the pulsating artery along the course of the vessels distally allows the vascular bundle to be exposed with minimal lateral dissection. The lymphatic vessels can be retracted laterally, and few of them need be transected. The exact center of such an incision leads to the uppermost segment of the superficial femoral vein. The junction of the superficial and profunda femoris is identified by a bulge in the superficial femoral just distal to this bifurcation (fig. 1). The artery overlies the vein in this region and is easily dissected free and held out of the way. It should not be isolated completely and retracted with ligatures or rubber tubing, since 1 case of thrombosis of the femoral artery due to rupturing the arterial wall, with resultant gangrene, has been seen in another hospital in which this method was used. The superficial vein is usually free of branches over its uppermost 1 to 2 cm. This enhances the isolation of this segment so that ligatures are easily placed at the upper and lower levels of the freed portion of the vein. It is important to open the vein and to remove existing thrombi from above as well as from below. A carefully used glass tubing suction tip aids in the removal of clots. Free bleeding from both ends of the vein is desirable. With strong suction after the thrombi are removed, one must guard against the removal of unnecessary blood. Our attention has been called to the reduction of the blood volume to shock levels by this method in an exceedingly short time.

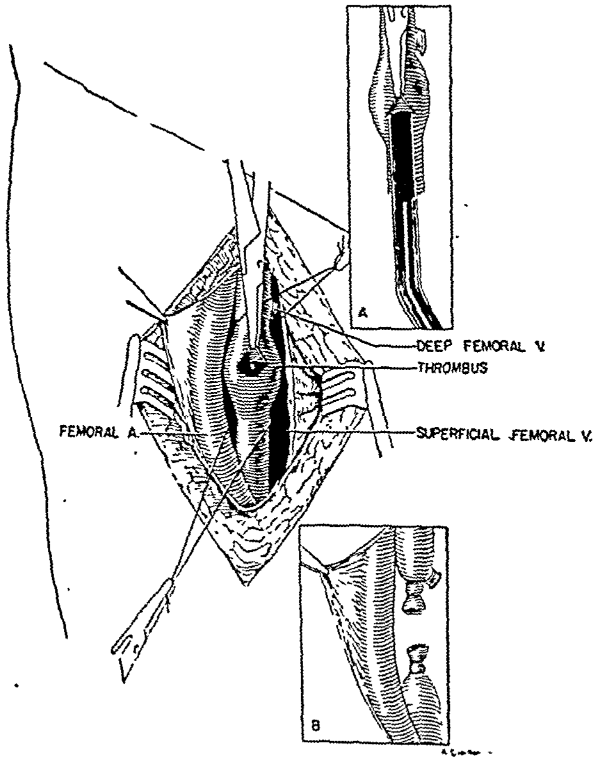

Fig. 1.—An artist's drawing to show the exposure of the superficial femoral vein with thrombectomy. *Note* the vertical incision used; the dilatation of the proximal end of the superficial femoral vein with the deep femoral vein joining it just above this bulge; the retraction of the femoral artery without completely isolating it. Inset *A* shows aspiration of the thrombus with a glass cannula. Inset *B* shows the completely divided superficial femoral vein. Each end is doubly ligated with a ligature and a transfixion suture of cotton and silk.

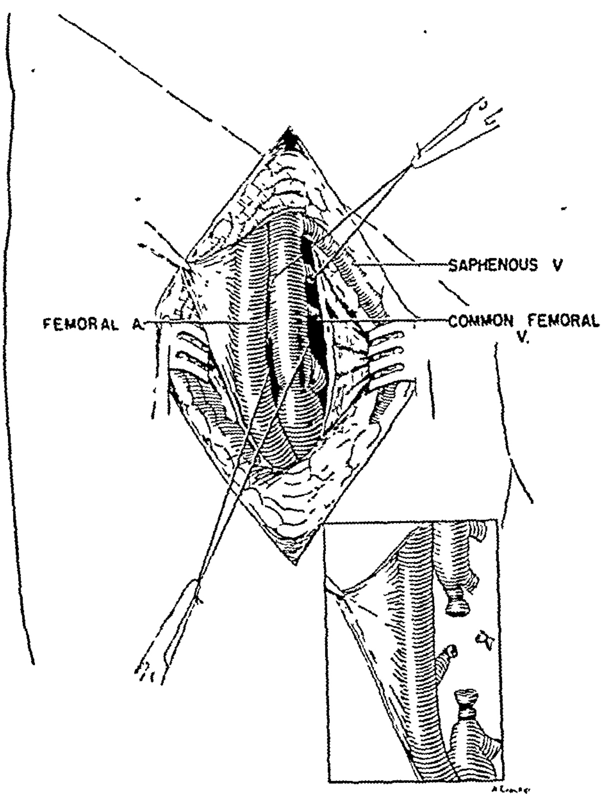

Fig. 2.—An artist's drawing to show the exposure of the common femoral vein proximal to junction of the superficial femoral and deep femoral veins. This is a more difficult operative procedure than interruption of the superficial femoral vein and should be used *only by* the experienced surgeon when thrombosis involves the two veins. The inset shows the completely ligated and divided vein and in addition two of its tributaries to give sufficient length of vein to permit safe interruption with division.

The importance of interrupting the superficial vein at the highest possible level is emphasized by our only fatal case of embolus following prophylactic interruption. The superficial femoral vein had been divided 3 cm. below the vena profunda femoris, and at autopsy this segment of vein was thrombosed. This could easily have acted as a nidus for the propagation of thrombus of sufficient extent to occlude the pulmonary arteries when the whole mass became detached eight days later. This patient was fat and had a large ventral hernia to be repaired. The prophylactic venous interruption was justified on the basis of age, obesity and the character of the operation needed. There was no evidence that phlebothrombosis existed at the time of interruption of the femoral veins, and it must be assumed that such a condition occurred afterward. It has been pointed out by Homans[8] and others that veins should be divided with a minimal segment below a free current of blood. Unless one isolates the vena profunda femoris sufficiently to determine the level of bifurcation of the common femoral vein there is danger of leaving too long a proximal stump of the superficial femoral vessel.

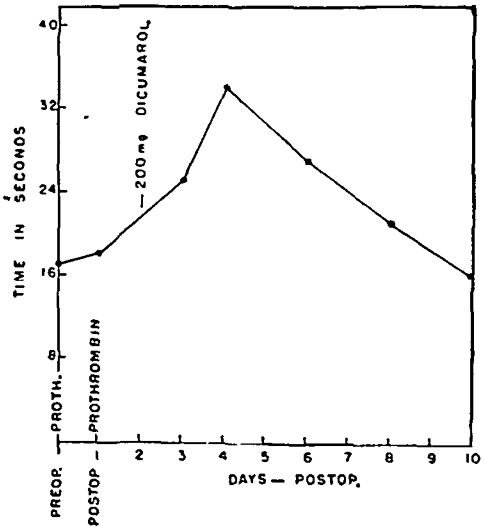

Fig. 3.—Typical response to one dose of Dicumarol.

Up to the time of this report there have been 1,281 patients subjected to interruption of the femoral veins for the prevention and treatment of thrombosis and embolism in the Massachusetts General Hospital (table 3). No patient has died and no patient has lost an extremity as a result of these procedures. The majority of the house cases have been operated on by the resident surgeons. This has caused us to minimize the operative procedure too much and has led men to undertake the operation who had not studied the problem. Confusion has occurred regarding the exposure of the desired segment of the vein, and serious complications have resulted. It has come to our attention that these unnecessary sequelae are obviously the result of carelessness. The unexpected tearing of a vessel with the resultant bleeding requires the calm and calculating orientation that comes with experience. Incredible as it may seem, we are aware of ligation of the femoral artery, which had been mistaken for the vein, in 1 instance.

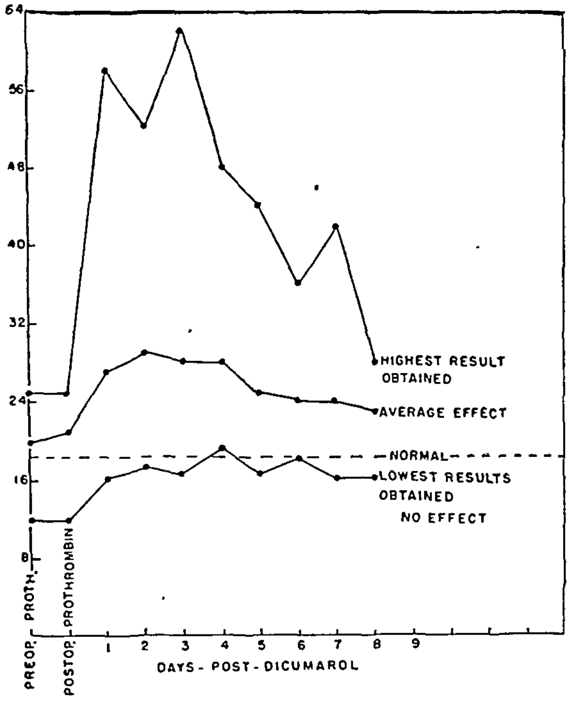

Fig. 4.—Composite curve of response of 165 patients to Dicumarol, measured by the Quick method, undiluted.

DICUMAROL

We have been interested in the use of all accredited methods of treating thrombosis and embolism. The anticoagulant drugs appeared at first likely to solve the problem. Our experience with heparin not being as satisfactory as that of Murray and Best,[9] we were well on our way with use of interruption of the femoral veins when Dicumarol became available. We watched the reports on the use of this drug with much interest and made some sporadic observations of our own. Finally we determined to carry out the controlled clinical experiments that are reported here. It seemed obvious that this drug could not be used indiscriminately on all types of patients and that complete laboratory check on the serum prothrombin level was necessary. It also became evident that the response to this drug was variable (fig. 3). Strong robust persons could tolerate more of it than the older and weaker patients. Since we have two surgical services of identical size, both of which handle the same types of patients, we were able to use one service as a control until the value of Dicumarol could be established in our clinic. We

[9] Murray, G. D. W., and Best, C. H.: Use of Heparin in Thrombosis, Ann. Surg. **108**: 163-177 (Aug.) 1938.

selected the age group 40 to 65 for this test and used small doses (200 mg.) of the drug as soon after operative intervention as the patient could take it, i. e., within twenty-four to seventy-two hours. Prothrombin determinations were made preoperatively on both services on patients in this age group. It was found that a small percentage of patients without known hemorrhagic tendencies had an elevated prothrombin time and that about the same number had a lower than normal level (table 4).

From Jan. 1, 1945 to June 1, 1946, 162 patients on the East surgical service received one or more 200 mg. doses of Dicumarol. About two thirds of these patients acquired an appreciable elevation of prothrombin time after one dose of the drug (figs. 4 and 5). About one half of the remaining number reached a satisfactory level after a second dose. Doubtless some of these could have been given larger doses with benefit. However, we have lowered the incidence of thrombosis and embolism to about 25 per cent of that seen in the control group (table 5). In no case did severe hemorrhage occur that could not have been accounted for otherwise. There was occasional evidence of ecchymosis at the site of needle punctures and some bleeding into the tissues near the operative wound, but such manifestations are often seen in patients not receiving Dicumarol. One patient bled from an intestinal anastomosis; this has occurred in other similar operations.

TABLE 5.—*Comparative Data*

Incidence of postoperative phlebitis in the age group 40 to 64 on the East surgical service (Dicumarol treated) and the West surgical service (control), Jan. 1, 1945 to June 1, 1946.

East Service (Dicumarol)	8 cases
West Service (control)	35 cases

In 1 instance of sudden death, thought to be due to embolus ten days after gastric resection, no explanation of death was found at autopsy. Permission for examination of the brain of this patient was refused by the family, and the possibility of cerebral hemorrhage could not be ruled out.

Some persons are decidedly resistant to the drug, while the prothrombin of others will rise from a normal of 18 seconds to 65 seconds on one 200 mg. dose. Figure 6 shows the curve of a resistant patient. This patient had had interruption of the superficial femoral vein and because of further infarcts had had ligatures placed around the common femoral veins. He continued to have infarcts, and Dicumarol was administered. In spite of the fact that no measurable rise in prothrombin time took place until after the third 200 mg. dose had been administered, he had no further infarcts after forty-eight hours had elapsed subsequent to the first dose.

Some of the inquiries which we receive indicate that we have failed to make clear what we mean by "prophylactic" interruption of the femoral vein. After we have evidence that thrombosis of the veins of the legs has occurred, we have looked on phlebotomy, thrombectomy and interruption of the femoral vein more as a method of treatment. In fact, this is done with the idea of preventing further and more massive emboli and is therefore somewhat prophylactic. In our use of this term, however, we have meant to imply that the veins were interrupted prior to any evidence of thrombosis or infarct in order to prevent the occurrence of these complications. As seen in table 4, we are performing the interruption of the superficial femoral veins before, at the time of or shortly after the chief operative procedure in the older age group of patients. These normal veins are interrupted before thrombosis exists, and *in no case save 1 instance (reported previously herein)* has there been any evidence of thrombophlebitis or embolism in this entire group.

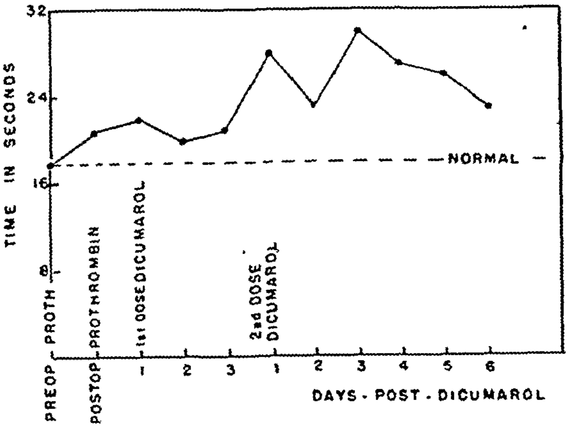

Fig. 5.—Response of 17 patients receiving two doses of Dicumarol, measured by the Quick method, undiluted.

When one considers that the patients selected for this prophylactic measure are—because of age, injury or disease—those most likely to have such a complication develop, it seems clear that greater use of this procedure should be made. Most of our early prophylactic interruptions were performed on the fracture service in patients with fractures near the hip joint. The high incidence of fatal embolus, particularly in intertrochanteric fractures, in our hospital made this procedure a welcome one to adopt. No fatal embolus has occurred in this group of patients since the prophylactic interruption of the superficial femoral veins has been the routine procedure. The urologic serice under the direction of Dr. Fletcher H. Colby and the gynecologic service under Dr. Joe V. Meigs have come to the conclusion that this procedure has much to commend it in preventing the development of thrombosis and embolism in elderly patients.

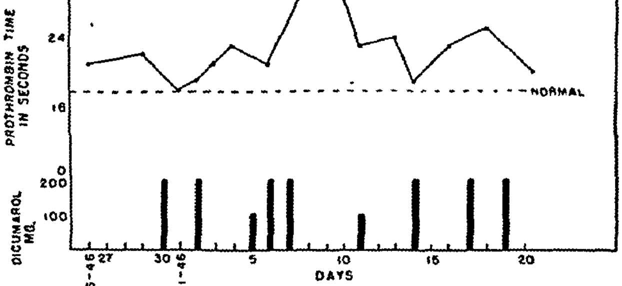

Fig. 6.—Response of Dicumarol-resistant patient, aged 29. Initial infarct, Feb. 24, 1946; bilateral interruption of the superficial femoral veins, February 22; infarct, March 24; bilateral interruption of the common femoral veins, March 25, and infarct, April 22, 1946.

It is difficult to convince the uninitiated that interruption of the normal superficial vein can be harmless. These patients not only have no complaints concerning their legs, but only the slightest amount of transient swelling is observed in the feet and ankles. That they are protected from thrombophlebitis by this method in nearly all instances, we are certain. We have indisputable evidence of the almost certain elimination of serious infarct. After such a procedure the chief complication now seen in modern surgical practice is avoided. It is quite probable that this method of prevention of thrombosis and embolism will be extended into the middle-aged group in many cases and occasionally will be employed in the younger patients whose injury or disease makes such a complication likely.

In this entire group of 1,300 patients there have been only 6 deaths in which subsequent emboli, as proved at autopsy, played a role. One of these interruptions was performed as a prophylactic measure and has been previously discussed. It is of great interest that in all 5 remaining cases interruption of the veins was done because of one or more previous pulmonary infarctions. Two of these procedures were performed at the level of the common femoral veins, and in 3 instances the superficial veins were divided. All these patients, save 1, were in the seventh or eighth decades and were generally debilitated. In each instance the previous infarcts had so reduced the pulmonary vital capacity that subsequent emboli of smaller size resulted in death. Had any of these patients had an initial prophylactic interruption of the femoral veins, as indicated, it is probable that even fewer deaths would have occurred.

SUMMARY AND CONCLUSIONS

1. Interruption of the normal superficial femoral veins at the highest level possible will protect the patient from thrombosis and embolism. This is a harmless procedure, when properly carried out, and should be done within seventy-two hours of the onset of rest in bed or surgical intervention. It is particularly indicated in aged and debilitated patients.

2. Dicumarol given in small doses postoperatively will reduce the incidence of thrombosis and embolism to at least 25 per cent of that seen in controls. It is imperative to have regular laboratory determinations on the plasma prothrombin time before and during the administration of the drug. In patients with hemorrhagic tendencies, of any age, and in arteriosclerotic persons it should not be used.

3. Phlebothrombosis and early thrombophlebitis is best treated by phlebotomy, thrombectomy and interruption of the superficial femoral veins on both sides. This reduces the risk of fatal embolism and diminishes subsequent infarcts. It also shortens the convalescence and reduces the inflammatory reaction in and about the deep veins.

4. If infarcts continue after interruption of the femoral veins, anticoagulants should be used. Heparin will elevate the clotting time immediately, and this anticoagulant effect can be maintained with the slower acting Dicumarol.

5. If thrombophlebitis progresses to produce pain and swelling after interruption of the femoral veins, procaine block of the lumbar sympathetic nerves will relieve pain and hasten recovery.

6. Interruption of the inferior vena cava should be performed only for repeated septic infarcts that by signs and symptoms indicate their source to be from the pelvic or iliac veins.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. AYCOCK AND HENDRICK, LOEWE AND HIRSCH, AND ALLEN, LINTON AND DONALDSON

Dr. Ross Veal, Washington, D. C.: Differential diagnosis is most important, for proper treatment depends on correct diagnosis. All of us should recognize acute thrombophlebitis, particularly the femoroiliac thrombophlebitis. Phlebothrombosis presents a much more serious problem. In the early stage there may be no symptoms. Later these cases may simulate thrombophlebitis in local and general signs and symptoms. Regardless of the stage, until complete organization there is always present the potential danger of pulmonary embolism. In my experience in 1 of every 4 patients, if the appropriate vein is not ligated, pulmonary embolism develops. With regard to the use of venograms as an aid in the diagnosis of venous thrombosis of the lower extremities, it was believed several years ago that this was going to be an important aid in determining the course of therapy. This led to a false sense of security in regard to some patients, because the venograms did not demonstrate the presence of a clot in their veins. These patients were allowed to go untreated and fatal pulmonary emboli occurred. I have therefore discarded the use of venograms as a measure of how these patients should be treated. As to the point of ligation, my associates and I differ somewhat from the Boston group. We have always felt that we should ligate a major vein through a normal segment of that vein above the clot. If ligation is performed through a diseased portion of the vein, too frequently thrombosis develops above the point of ligation. Our rule now is to ligate through a normal segment of the vein, above the diseased portion or clot and just distal to a main tributary. This means that ligation may be performed through the femoral vein just below the saphenous in some and through the common iliac vessels in others; in still others it becomes necessary to ligate the vena cava. We have used local anesthesia in many patients, but we now favor the use of pentothal sodium and oxygen. We have often found that after pulmonary infarcts these patients are decidedly apprehensive and sometimes difficult to handle under local anesthesia. We believe that under an expert anesthetist anesthesia by means of pentothal and oxygen works well and is safe in such patients. In ligation of the major veins there is a danger which has not been stressed, and that is a sudden congestion of the limb below the level of ligation. We have had 4 instances in which, immediately after ligating a major vein, the leg became enormously swollen and the veins tremendously dilated, with petechial hemorrhages occurring throughout the tissues. Fortunately we recognized this quickly and by elevation of the leg to an extreme level and prompt blocks of the sympathetic nerves the circulation was quickly corrected. All 4 patients recovered without any loss of tissue and without any evidence that the congestion had caused permanent damage. I do not consider that after ligation of the major veins the extremity is perfectly normal. One must anticipate some swelling in the majority of these cases, depending on how extensive the thrombosis was at the time of ligation. If the clot has extended all the way up to the femoral triangle most of these patients are going to have some postoperative edema, but if that edema is controlled from the onset many will recover completely. However, if swelling of the leg continues, we may expect trouble with the skin, such as eczema and ulcers. Therefore, all our patients leave the hospital with a properly fitted elastic stocking, which they wear until there is no longer any swelling.

Dr. Alton Ochsner, New Orleans: Whereas in Boston they ligate everything, in New York they ligate nothing. We take the rational middle ground and ligate those that should be ligated and don't ligate those that need not be ligated. Dr de Bakey and I believe that there is a definite difference between the two types of venous thrombosis—phlebothrombosis and thrombophlebitis—and although the patient with phlebothrombosis who is fortunate enough not to die as a result of a detachment of his thrombus will ultimately develop an inflammatory process so that the thrombus becomes attached, that is not the way most cases of thrombophlebitis begin. On the other hand, we are convinced that thrombophlebitis usually begins as a primary inflammatory lesion in the vein. The cause may be bacterial, it may be toxic or it may be allergic, but the process fundamentally is different from that in phlebothrombosis. Dr. Hendrick has emphasized the importance of prophylaxis; this is extremely important. Not only can pulmonary embolism be prevented by preventing the detachment of the clot when it is once formed, but one can usually prevent the formation of the thrombus. Dr. Hendrick mentioned the value of certain postures and the danger of other postures. We go farther than that. We feel that any patient past 40 years of age—and we would agree with Dr. Allen that age is a factor—who has trauma from any cause, operative or otherwise, should have his lower extremities compressed from his toes to his groin and should be made to contract his muscles actively, and particularly his calf muscles, against a resistance. I thoroughly agree with Dr. Linton that ambulation means ambulation, and the worst thing that one can do is let a patient get out of bed and sit. It is far better that the patient remain in bed in a horizonal position and actively and forcibly bend or flex his foot against a resistance. There will be a few cases of phlebothrombosis which will develop even under this therapy. It is a rule on our service that twice daily the calves of patients are compressed, and forceful dorsal flexion of the foot is carried out, as suggested by Dr. Homans. In this way we can detect phlebothrombosis in its incipiency and, as Dr. Linton has suggested, we think that these cases require ligation. I have seen too many patients in consultation in whom anticoagulants have been used with the idea that the patient was perfectly safe, and yet they have had repeated emboli. I am sure that anticoagulants will prevent the formation of new thrombi, but I am also sure that they will not guarantee against the detachment of the thrombus already there. I have no objection to anticoagulants; I think it is well to use them. The use of anticoagulants is primarily prophylactic, as Dr. Linton says, but it is dangerous to use and to rely on such drugs alone, because the clot that is already there and not detached can still become detached, even though one does prevent the formation of other thrombi.

Dr. Frederick W. Bancroft, New York: I wish to protest against Dr. Ochsner's statement that we never ligate veins in New York. It has been my good fortune to work with Dr. Loewe in several cases and to have used his menstruum in at least 10 patients, independently. There is no doubt that the heparin-Pitkin menstruum provides the anticoagulant effect and is infinitely superior to the continuous intravenous administration of heparin. I agree with Dr. Loewe that venostasis is a decidedly important factor in thromboembolic diseases. As an example, I might mention 4 cases of phlebothrombosis of the femoral vein occurring during rest in bed, after an attack of coronary occlusion. After the removal of the clot from the iliac vein it was possible to mobilize these patients immediately, whereas the use of anticoagulants would have kept them in bed for a longer period. While I agree with Dr. Loewe that a majority of cases of phlebothrombosis originate in the deep veins of the calf, there is another type starting from the uterine veins, and pulmonary infarcts have resulted before there is evidence of retrograde thrombosis of the thighs or legs. There are three types of cases in which we would hesitate to use anticoagulants; first, immediately after pregnancy; second, in phlebothrombosis following hemiplegia from hemorrhage, and third, in phlebothrombosis following coronary occlusion. I disagree with Allen and his co-workers that it is necessary to ligate both sides every time. In my experience if the thrombus starts from the veins in the calf and is seen early and that vein is ligated, I have never seen it occur on the other side. On the other hand, when it has started in the pelvis, I have had experience to indicate that the veins on both sides should be ligated simultaneously. Dr. Loewe has made a great contribution in his heparin-Pitkin menstruum, in making the administration of heparin much simpler, safer and less expensive.

Dr. Geza de Takats, Chicago: In a group of 251 patients on our service, we have seen 1 fatal and 2 nonfatal pulmonary emboli, so that our treatment has justified itself at least in a small series of cases. At least 40 per cent of these patients are admitted or are seen with thoracic symptoms before any localizing symptoms occur in the periphery. With the combination of oxygen, atropine and papaverine, and also heparin, a number of lives can be saved. It is difficult to put this on a statistical basis, because a number of patients with pulmonary emboli recover, but the response to this treatment is often dramatic. Symptoms of a pulmonary embolus are due to a sudden obstruction of the pulmonary arterial tree plus an intense vasospasm of the unaffected part of the pulmonary artery, a bronchial spasm and a sudden coronary insufficiency. When the origin of the embolus is recognizable we ligate above the level of the recognized thrombus. This might be the superficial femoral, the common iliac or the vena cava. When the origin of the embolus is unknown, we do not use any phlebograms but institute anticoagulant therapy, by which we mean heparin, for two days in intermittent doses—50 mg. every four hours intravenously—and Dicumarol. It is important that Dicumarol be given in adequate amounts, so that the isothrombin level is at least 50 per cent below normal. If one does not do that, one is not really protecting the patient. One or two doses of 200 mg. of Dicumarol are nonprotective. We have discharged a number of patients on small amounts of Dicumarol; those, for instance, who have had arterial emboli following coronary occlusion. Such patients take 200 or 300 mg. of Dicumarol every week, and the incidence of emboli in this group has been just as high as in the ones who have not received it; this drug must be given in therapeutically effective doses. When one suddenly stops the administration of heparin or of Dicumarol, there may be a thrombosis. We have observed such an occurrence in 3 instances. If treatment with heparin or Dicumarol is to be discontinued, it must be stopped slowly, and it must not be continued in the ambulant patient. There is no reason why the surgeon should not use anticoagulants in conjunction with surgical therapy, just as a surgeon will amputate a diabetic toe and still use insulin. Dr. Loewe's subcutaneous heparin is the most promising new development, and perhaps improvements can be made to make the solution less painful and irritating so that the general medical practitioner can use it. At present the combination of surgical treatment with anticoagulant therapy gives the smallest incidence of fatal pulmonary emboli.

Dr. Kurt Lange, New York: After we had found that heparinization was able to prevent the gangrene subsequent to frostbite, Dr. Loewe was kind enough to let us try some of our frostbite lesions on his patients who were to be heparinized anyway for endocarditis, and although the heparinization in these patients with the heparin-Pitkin menstruum succeeded excellently in keeping the clotting time at the desired level, to between 30 and 60 minutes, it was rather conspicuous that the patients had great pain at the site of the injections. We do not put too much attention on that, for the advantage of an intramuscular heparin is such a great one, especially in the treatment of thromboembolic disease, that we think it would not matter whether or not it was painful. We were especially enthusiastic, for we thought that in our animal experimentation we would now be able to give heparin once a day and then forget about the animal for twenty-four hours. When we did that we found that of 160 animals thus treated (120 rats and 40 rabbits) 150 died at the third or subsequent day, with the clotting time between 30 and 60 minutes at the time of their death. At autopsy it was found that all of them had died from anemia, sanguinating into the site of the injection, where tremendous hematomas were found. That means that apparently the small capillary bleeding which was caused by the injection could not stop when large deposits of heparin were underlying this bleeding. I would like to ask Dr. Loewe whether in his cases in which autopsies were performed these sites of injection were examined or whether aspirations were done at the sites of injection to find out if the pain is not the result of a subcutaneous hematoma which, in the human being, does not become as great in extent on account of the local circumstance of the tissue.

Dr. Ralph Adams, Boston: I wish to mention another group treated in Boston. In something over 9,000 operations performed during the last four years, we have recognized thromboembolic phenomena in 170 patients treated with heparin and Dicumarol and in 8 by ligation. We lost 1 patient who had been adequately treated with the anticoagulants; we lost

1 patient, after bilateral ligation of the vein, who had one single dose of Dicumarol and a second patient who was Dicumarol-resistant. In this same period we had 40 deaths from pulmonary embolism in patients who had no recognized sign of thrombosis or embolism preceding the fatality. The question is, should we have performed ligations to prevent this tragedy in all patients over the age of 40, who in our group represent nearly 50 per cent of those having major operative procedures? That would amount to approximately 4,500 ligations. The second question is, if we are to use anticoagulation prophylactically, when should it be started postoperatively? Since we have started the energetic use of foot exercises, with preoperative instructions in writing in all languages necessary to be read by our heterogeneous group of patients the incidence of thromboembolic phenomena has been reduced by about 50 per cent.

Dr. James W. Hendrick, Baltimore: There are so many important phases of this subject, it is difficult to cover them all in the time allotted. Since the University of Maryland hospital is a state institution, a large number of patients in the older age group are admitted. Consequently, an appreciable number are candidates for venous thrombosis, unless caution is exercised to prevent this complication. We consider, as Dr. Ochsner has stressed, that prevention is the main factor. Members of our resident and nursing staff are taught to carefully note any indication of this complication. Also each patient is given instructions to help prevent it, as was mentioned by Dr. Adams of the Lahey Clinic. Relative to Dicumarol therapy, we have found it to be contraindicated in prostatic and thyroid surgery, and in disease of the liver. We think it should be used with caution and only given when careful determinations of prothrombin time can be made every twenty-four hours. We have seen several patients that were sent in from the surrounding territory in whom massive hemorrhages had developed following Dicumarol therapy after a surgical procedure. Such patients required large doses of vitamin K to prevent death. We would like to stress again that a careful differential diagnosis should be made between phlebothrombosis and thrombophlebitis. If phlebothrombosis is present paravertebral blocks should not be done. But thrombophlebitis will respond to paraverterbral blocks. This procedure was first reported by Dr. Ochsner and his group. We inject the first, second, third and fourth lumbar ganglions with 10 cc. each of a 1 per cent solution of procaine hydrochloride. We also inject the second and third ganglions each with 10 cc. of monobromosaligenin (Bromsalizol) solution. The latter solution was developed by Dr. Ferdinand Lee and his co-workers at the Baltimore City Hospital and the Johns Hopkins Hospital. The procaine solution acts instantly but begins to lose its effect after twelve hours to twenty-four hours; monobromosaligenin is slower, but the effect will last from four to eight days. This procedure is not difficult to execute and can be used by physicians over the entire country, who have been properly trained in the technic of administration.

Dr. Robert R. Linton, Boston: In answer to Dr. Adams' question, what are we going to do with 4,500 patients over 40 years of age who undergo major surgical operations at our clinic? I did not mean to infer that every patient over 40 years of age should have his femoral veins interrupted. I meant to stress the importance of prophylactic interruption of the femoral veins in patients over 50 years of age who are operated on for abdominal cancer. It is possible after a little training to do bilateral interruptions of the superficial femoral veins in a short while. It usually takes not longer than twenty minutes. Until it has been proved that prophylactic interruption of the superficial femoral veins is not adequate protection against pulmonary embolism, I believe that it is well worth while spending anywhere from twenty minutes to half an hour to perform this simple procedure. To date we have carried out this procedure in some 358 patients. There was 1 death in this group of prophylactic interruptions. At autopsy it was seen that the interruption was about 3 cm. below the junction of the superficial and profunda femoris veins. This definitely was a technical error, as a thrombus was found in this blind segment of superficial femoral vein below the profunda branch. The junction of the superficial and the profunda femoris veins must be visualized, and if the superficial femoral vein is tied it must be done at the junction, so that there is no blind segment of vein distal to the point at which the superficial and profunda femoris unite to form the common femoral vein. Anticoagulants should be used mainly in the prophylaxis of venous thrombosis. They should be used also after the femoral veins have been interrupted if a secondary sublethal embolus develops. One of the chief arguments against interruption of the femoral veins is that one must surely damage the extremity by interrupting its main venous channel. At first we were fearful of this, but after well over 2,000 such interruptions without the development of any serious consequences in these patients, we feel assured that it is a safe procedure. We as well as others are now interrupting the femoral veins in the postphlebitic group of patients that present the chronic indurated ulcers that have been so hard to heal in the past. From a physiologic point of view it must be realized that these large venous channels in the lower extremity are not necessary as conduits for blood; they are mainly reservoirs of blood which can be interrupted without damaging the patient's health or his extremities.

Dr. Leo Loewe, Brooklyn: We have successfully treated with heparin Pitkin menstruum patients in whom bilateral ligation of the femoral veins failed to prevent recurrent pulmonary embolization. Dicumarol failures which were referred to us were then successfully treated with heparin/Pitkin menstruum. The disadvantages of Dicumarol have been pointedly demonstrated by Dr. Linton; the dosages are haphazard, and propagation of thrombus—even pulmonary embolization—can occur despite apparently adequate doses. In addition to being toxic and difficult to control the action of the drug is delayed. Its chief virtue is that it can be administered by mouth. The issue of venous ligation versus anticoagulant therapy requires more statistical proof before it can be resolved. We have had no instance of lethal pulmonary embolization since our optimum treatment program has been established. The painful local reaction mentioned by Drs. de Takats and Lange has also been observed with Pitkin menstruum preparations containing agents other than heparin. This objection has now been remedied by the use of more physiologically acceptable gels. There is the question of local hemorrhage raised by Dr. Lange. His experience has been limited to animal experiments. Those of us who have used the heparin/Pitkin menstruum, including Drs. Bancroft, Blakemore of the Columbia-Presbyterian group and Evans of the Lahey Clinic, have never encountered anything that has purported to be hemorrhage. In heparinizing over 200 rabbits and about 400 patients, totaling several thousand injections, we did not see the reactions described by Dr. Lange in his experiments with rats. The reason is obvious. If he would analyze his dosages he would find that in a definite attempt to raise the coagulation time to levels consistent with his experimental requirements he has given his rats 15 to 20 mg. of the drug daily. This is the equivalent by weight to a daily human dose of about 2,500 mg. as contrasted with the recommended human dose of 300 mg. every other day.

Pulmonary Air Embolism.—Basic to an understanding of pulmonary (venous) air embolism is a clear conception of its differentiation from the arterial form of air embolism. Although both depend for their effects on the presence of air in the circulation, the site of entrance of the air determines its distribution within the vascular system and is therefore extremely important. In the pulmonary form, air enters one of the systemic veins and is carried to the right heart and pulmonary circulation and depends for its effects on mechanical obstruction of the outflow tract of the right ventricle. Fairly large amounts of air are needed to produce this effect. In arterial embolism the air gains entrance to the pulmonary venous channels and is propelled from the left ventricle to those systemic arteries which supply the superiorly located portions of the body. Since a small amount of air can effectively block a medium sized artery, serious consequences may result when a few cubic centimeters of air enter the pulmonary vein and are carried into either the coronary, or cerebral, circulation, or both. . . . As would be expected, the clinical picture in the two forms of embolism is totally different.—Durant, Thomas M.; Long, Joan, and Oppenheimer, Morton J.: Pulmonary (Venous) Air Embolism, *Am. Heart J.*, March 1947.

THE TREATMENT OF SERUM SICKNESS WITH BENADRYL

J. CYRIL PETERSON, M.D.
and
LINDSAY K. BISHOP, M.D.
Nashville, Tenn.

The recent report of State and Wangensteen[1] was the first concerning the use of a drug having a satisfactorily specific therapeutic action in the treatment of serum sickness. They successfully employed intravenous injections of procaine hydrochloride to abolish the manifestations of serum sickness. In the past two years we have had an opportunity to observe the effect of Benadryl hydrochloride, a drug related to procaine, in the treatment of 10 patients with serum sickness. These patients responded to the oral administration of the drug.

STUDY MATERIAL

Serum sickness developed in our patients as a complication of serotherapy for a variety of conditions; 4 infants and 1 child from treatment with meningococcus antitoxin, a fairly crude horse serum preparation; 1 child from treatment with polyvalent antivenin, also a relatively crude horse serum preparation; 1 infant from treatment with diphtheria antitoxin, a more highly refined horse serum preparation, and 2 infants and 1 child from treatment with type B anti-Hemophilus-influenzae serum, a highly refined rabbit serum preparation. Brief reports of the individual cases follow.

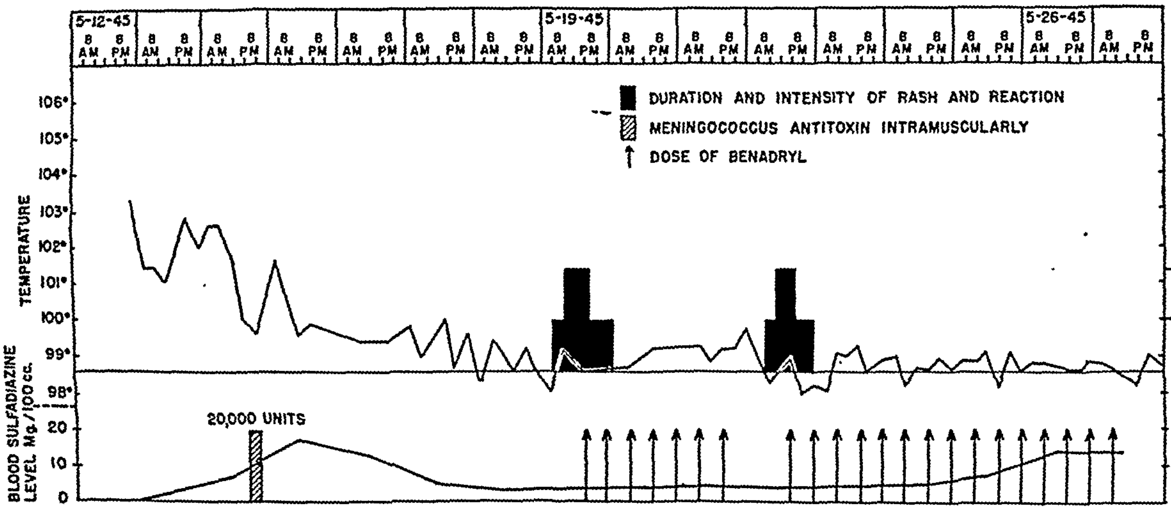

Fig. 1 (case 2).—Serum sickness following meningococcus antitoxin and its response to therapy with Benadryl hydrochloride.

REPORT OF CASES

Case 1.—W. N., a white boy aged 2 months, received 10,000 units of meningococcus antitoxin intramuscularly on March 7, 1945, for meningococcic meningitis. The preliminary intradermal sensitivity test was negative. Ten days later there developed a generalized urticarial eruption. Treatment with Benadryl hydrochloride, 50 mg. orally every twelve hours, was instituted. There was no response during the succeeding forty-eight hours. The dosage was increased to 50 mg. of the drug every six hours, and the rash disappeared completely after the second dose. The therapy was discontinued after another twenty-four hours. There was no recurrence of the rash. The rash was this patient's sole manifestation of serum sickness.

Case 2.—C. S., a white boy aged 3 months, received, by intramuscular injection, 20,000 units of meningococcus antitoxin on May 14, 1945, in the treatment of meningococcic meningitis. He had shown a negative intradermal sensitivity test. Five days later a generalized urticarial eruption appeared. Benadryl therapy, 50 mg. orally every eight hours, was instituted on May 19, and the rash completely disappeared following the second dose. Therapy was discontinued on May 21, and the rash reappeared on May 22. It again disappeared after the second 50 mg. dose with an eight hour interval. Therapy was continued until May 27. There was no subsequent recurrence of symptoms. Elevation of the temperature to 99.8 F. was the only other manifestation of serum sickness in this case. The response to therapy is shown in figure 1.

Case 3.—P. P., a white girl aged 2 years, who had meningococcic meningitis, contracted an urticarial eruption on Feb. 11, 1945, eight days after the administration of 20,000 units of meningococcus antitoxin. The intradermal sensitivity test had been negative. Treatment with Benadryl, 50 mg. every twelve hours, failed to relieve the symptoms, but on May 14 an increase of the dosage to 50 mg. of the drug every eight hours resulted in complete disappearance of the rash. It was thought that the serum sickness which was mild might have terminated. The therapy was stopped, and in fourteen hours there was a recurrence of the rash. Treatment with 50 mg. of Benadryl every eight hours relieved all symptoms. Treatment was discontinued without recurrence on May 16. This patient showed only an elevation of temperature to 100 F. in addition to the urticarial rash.

Case 4.—S. H., A white boy aged 8 years, received 15 cc. of antivenin on Aug. 1, 1945, for a copperhead (Agkistrodon mokasen) snake-bite. An intradermal test with the antivenin had been negative. A generalized macular erythematous eruption developed nine days later, and the boy was obviously ill and irritable, but no other symptoms of serum sickness were observed. Treatment with Benadryl, 50 mg. orally every four hours, caused the disappearance of the rash after the second dose. He was also generally improved. The Benadryl dosage was reduced to 50 mg. every eight hours and was discontinued after three such doses. Fourteen hours later the rash reappeared. Therapy with 50 mg. of Benadryl every eight hours was reinstituted, and there was no recurrence when it was discontinued on August 27.

Case 5.—B. M., a white boy aged 4½ years, with meningitis due to type B H. influenzae had a diffuse macular erythematous eruption which developed ten days after the initial intramuscular injection of type specific rabbit antiserum on Dec. 3, 1945. He received 125 mg. of agglutinin antibody nitrogen equivalent on the first day and an additional 25 mg. on the second and fourth

Benadryl, beta-dimethyl aminoethyl benzohydryl ether hydrochloride, was supplied by Parke Davis & Company.

[1] State, D., and Wangensteen, O. H.: Delayed Serum Sickness, J. A. M. A. **130**: 990 (April 13) 1946.

days. Shortly after the rash appeared he was given Benadryl, 50 mg. orally. The rash faded promptly but recurred after sixteen hours. Treatment with 50 mg. of the drug every eight hours resulted in disappearance of the rash after the second dose. At the end of the third day after the onset of serum sickness administration of the drug was discontinued without recurrence of the rash. There were no other manifestations of serum sickness in this case.

Case 6.—R. S., a boy aged 2 years with meningitis due to type B *H. influenzae* was given specific rabbit antiserum containing 100 mg. agglutinin antibody nitrogen equivalent intramuscularly on Jan. 6, 1946. The intradermal sensitivity test with a 1 : 10 dilution of serum was 2 plus positive. Serum containing 25 and 50 mg. agglutinin antibody nitrogen equivalent was administered on the second and third days, respectively. On January 16 there developed a macular erythematous eruption and urticaria. The child also vomited but did not show other manifestations of serum sickness. He was given 50 mg. of Benadryl initially, followed in four hours by 40 mg. of the drug. There was little improvement in the rash so the dosage was increased to 50 mg. every four hours, with some, but incomplete, improvement. After three such doses a further increase to 60 mg. of the drug every four hours resulted in pronounced improvement; the urticarial component disappeared, but there was some rash throughout the forty-eight hours of therapy at this level. However, the patient was much less irritable and the vomiting associated with the rash ceased.

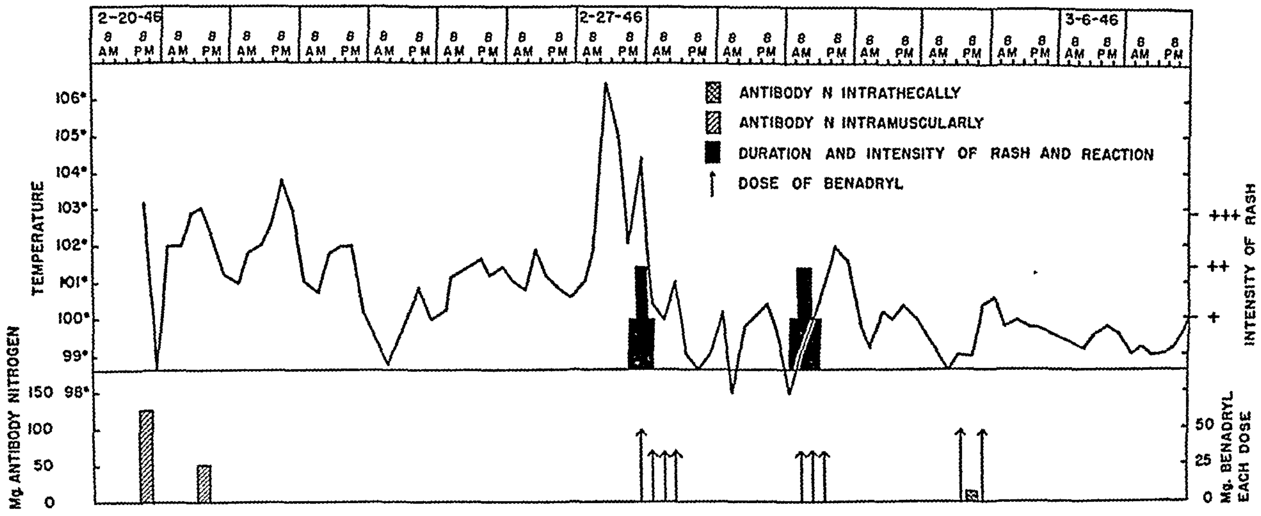

Fig. 2 (case 10).—The response of serum sickness following the administration of anti-*H. influenzae* serum type B (175 mg. of agglutinin antibody nitrogen equivalent) to treatment with Benadryl hydrochloride.

Case 7.—F. T., a white boy aged 20 months, was admitted to the hospital on Jan. 11, 1946 with acute laryngeo-tracheobronchitis. He had received injections of 10,000 units of diphtheria antitoxin on each of three successive days prior to hospitalization. On January 16, eight days after the first injection of antitoxin, a generalized erythematous macular eruption developed. Treatment with 50 mg. of Benadryl every four hours was started. In two hours after the initial dose the rash had completely disappeared. No recurrence was noted when therapy was discontinued on January 18. This was an extremely mild case with no symptoms except the rash.

Case 8.—R. L., a white girl aged 4 months with meningococcic meningitis, was given 10,000 units of meningococcus antitoxin intramuscularly on Jan. 30, 1946. The conjunctival sensitivity test with a 1 : 10 dilution of the antitoxin had been negative. Because of the extremely poor condition of the patient an additional 10,000 units of antitoxin was given about ten hours after the initial dose. On February 4, five days after the initial administration of antitoxin, there developed a mild urticarial eruption on the abdomen of the patient. The next day the rash was generalized and was confluent over the trunk. The infant also vomited several times, but there was no fever or lymphadenopathy. Treatment with elixir of Benadryl, 30 mg. every four hours, was instituted, and only a few lesions remained one hour after the second dose had been given. The patient, however, frequently vomited the elixir and on February 6, after she had lost two doses in this manner, the rash recurred. Though the dose of elixir was increased to 60 mg. every four hours the continued vomiting was enough to void the treatment, and the rash persisted. Benadryl powder, 100 mg., was substituted for the elixir on February 8. The rash faded completely within four hours. Maintenance therapy with 50 mg. of Benadryl every four hours was continued. No recurrence of symptoms was noted subsequent to cessation of therapy on February 10.

Case 9.—J. M., a white girl aged 3½ months with meningitis due to the Diplococcus mucosus was given 10,000 units of meningococcus antitoxin on Feb. 2, 1946, after a negative conjunctival test with a 1 : 10 dilution of the antitoxin. Four days later there developed a rather fine diffuse macular and urticarial eruption; she began to vomit and her temperature rose from 99 to 102.8 F. Because of the seriousness of her reaction she was given a large initial dose of Benadryl, 100 mg., which was followed in four hours by a 50 mg. dose. The rash cleared completely in about one hour after the second dose. The fever and vomiting ceased twelve hours after the initial dose of Benadryl. Benadryl therapy was discontinued after five doses, and in twelve hours the rash reappeared. Benadryl therapy was reinstituted, the patient receiving 75 mg. initially followed by 50 mg. every four hours for an additional two days. There was complete relief with no recurrence after the discontinuance of treatment.

Case 10.—C. E., a girl aged 9 months with meningitis due to type B. H. influenzae received an intramuscular injection of type specific rabbit antiserum containing 125 mg. agglutinin antibody nitrogen equivalent on Feb. 20, 1946. The preliminary intradermal sensitivity test had been negative. On the following day an additional 50 mg. was given because she had an inadequate serum antibody titer. Seven days after the initial serum injection there developed a macular erythematous urticarial eruption over the entire body of the patient. She had shown progressive improvement to this point, though the infection had not been completely controlled. With the development of the serum reaction she became critically ill, showing Cheyne-Stokes respiration, temperature elevation to 106.4 F. and slight cyanosis. Treatment with Benadryl, 50 mg. for the initial dose and 37.5 mg. every four hours for four doses, resulted in disappearance of the rash and definite improvement in her general condition. At the end of twenty-four hours the administration of Benadryl was discontinued because of increasingly severe vomiting. The child also had as a further complication moderately severe alkalosis as a result of the sodium bicarbonate given in conjunction with her sulfadiazine therapy. Thirty-six hours later there again developed fever and a rash, but the patient responded rapidly to therapy with Benadryl, 3 doses of 37.5 mg. each given at four hour intervals. On March 4, forty-eight hours after receiving the last dose of Benadryl, she was given 15 mg. of type specific rabbit serum intrathecally. A prophylactic dose of 50 mg. of Benadryl was given at 4 p. m., the serum was injected at about 5 p. m. and an additional dose of Benadryl was given at midnight. Her recovery from this point was uneventful. There was no evidence of immediate or delayed serum reaction after the intrathecal injection. This patient's response to Benadryl therapy is summarized in figure 2.

COMMENT

Serum sickness is a fairly frequent complication of heterologous serotherapy. While it occurs much more commonly after the use of crude serum or relatively crude preparations, such as the currently available meningococcus antitoxin, it also follows the use of highly refined antibody globulin preparations. This is shown by the occurrence of serum sickness in cases 5, 6 and 10 after the administration of highly refined anti-H. influenzae serum.

The occurrence of serum sickness constitutes a disagreeable and troublesome illness in otherwise healthy persons, but it is often a serious complication when it occurs during the course of meningitis, tetanus or diphtheria.

The histamine concept of serum sickness, first advanced by Dale and Laidlaw[2] in 1910, has gained wide acceptance. The studies of Loew and his associates[3] showing the comparative efficacy of beta-dimethylaminoethyl benzohydryl ether hydrochloride (Benadryl) in combating histamine aerosol-induced bronchiolar constriction in guinea pigs suggested that the drug would be useful in the treatment of a variety of allergic disturbances. Although a number of early reports have appeared showing its effectiveness in the treatment of urticaria, there has been little said specifically in regard to its effectiveness in serum sickness. Friedlaender and Feinberg[4] report the control of 3 cases of "serum sickness-like" reactions associated with penicillin therapy, and Todd[5] reported on the control of whealing reactions subsequent to skin tests with horse serum, but we have been unable to find any reports on the use of Benadryl hydrochloride in the treatment of true serum sickness.

The report of State and Wangensteen[1] and more recently that of Applebaum, Abraham and Sinton[6] concerning the use of intravenous procaine therapy for serum sickness attests the need of remedies more effective and certain than epinephrine, theophylline ethylenediamine and calcium gluconate.

Our studies have shown that the early, and presumably the later and severer, symptoms of serum sickness can be completely controlled by Benadryl. The mode of action of this drug has not been entirely explained. It has been shown that it abolishes the vasodilatation from histamine and that it serves generally as an antispasmodic agent. Repeated oral doses of Benadryl as high as 8 mg. per pound (0.5 Kg.) of body weight (in small infants) were tolerated without side reactions. Nausea did occur in several instances but was troublesome only once, in case 10. It occurred more frequently in the use of the elixir than in the use of the powder. We encountered no difficulties in the use of the powder even in small infants, into whose mouths the capsule was simply emptied, using care to prevent aspiration. There was no observable local effect on the mucous membranes, though such topical application serves to partially anesthetize the tongue and buccal surfaces.

The effective dose of Benadryl for the treatment of different allergic manifestations is still being studied. From our cases it is apparent that doses of 50 mg. of the drug may not always be adequate to control the rash of serum sickness even in an infant 4 months of age, as in case 6, or a child aged 2, as in case 7. It is probable that the drug is effective in proportion to its concentrations in the tissues and that it will require two or three times as much per pound (0.5 Kg.) of body weight to control symptoms in infants as compared with adults.

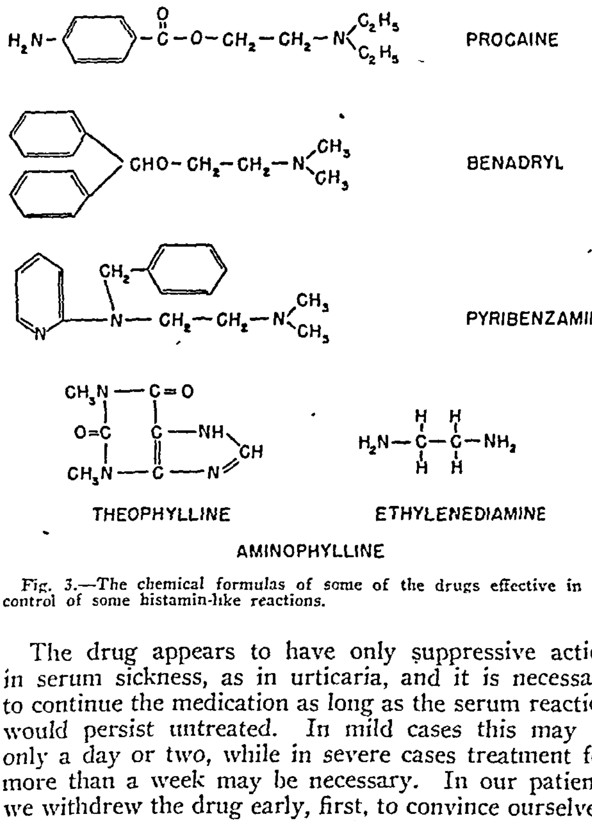

Fig. 3.—The chemical formulas of some of the drugs effective in the control of some histamin-like reactions.

The drug appears to have only suppressive action in serum sickness, as in urticaria, and it is necessary to continue the medication as long as the serum reaction would persist untreated. In mild cases this may be only a day or two, while in severe cases treatment for more than a week may be necessary. In our patients we withdrew the drug early, first, to convince ourselves, by allowing relapses, that the drug was truly effective and that we were not simply observing mild abortive reactions; and second, to ascertain how long the effect of an individual dose would last. The relapses which followed withdrawal in several instances confirm the real effect of the drug. The period of effect of the drug is not so clear but would seem from our cases to be somewhere between six and twelve hours, though the effect of extremely large doses might persist longer. We cannot say whether or not there is an appreciable cumulative effect when doses are given less frequently than every eight hours, but doses at four, six and eight hour intervals seem to have some cumulative effect. This was indicated by the fact that several times a second dose succeeded in eliminating s residual from the first dose. In every instance 100 mg. of the drug completely abolished all manifestations of the serum sickness within a period of two to three hours.

[6] Appelbaum, E.; Abraham, A., and Sinton, W.: A Case of Serum Sickness Treated with Procaine Intravenously, J. A. M. A. **131:** 1274 (Aug. 17) 1946.

It is probable that future studies with the intravenous use of Benadryl will result in the development of improved technic for the control of the major crises in serotherapy.

It is interesting to note that the drugs recently investigated and found of value in the control of the histamine-like allergic reactions—theophylline ethylenediamine (aminophylline), Benadryl, procaine, pyribenzamine (N′pyridyl-N′benzyl-N-dimethylethylenediamine) and others—show certain structural similarities. All of them contain an aminoethyl or an ethylene diamine group[7] (fig. 3).

SUMMARY AND CONCLUSION

1. Ten cases of serum sickness have been treated successfully with Benadryl hydrochloride; 9 of the 10 cases were completely controlled, and the other was much improved.
2. Adequate therapy with this drug was found to consist of 50 to 100 mg. doses given at six to eight hour intervals and continued for the duration of the serum sickness.

Clinical Notes, Suggestions and New Instruments

METHEMOGLOBINEMIA IN AN INFANT AS A RESULT OF THE ADMINISTRATION OF BISMUTH SUBNITRATE

WILLIAM M. WALLACE, M.D.
Boston

Despite occasional reports[1] of fatalities or near fatalities from the administration of bismuth subnitrate the drug is still commonly prescribed in the treatment of diarrheal disease in infants as well as older children and adults. The statement is made in Useful Drugs[2] under the section on bismuth compounds that "the salt most frequently used is bismuth subnitrate, but since this sometimes produces poisonous effects, the subcarbonate is preferable." The reduction of nitrate to nitrite by the intestinal flora, the absorption of the latter and the subsequent development of methemoglobinemia is supposed to be a recognized danger but a seldom considered sequence. The following case report is considered worthy of note to emphasize the possibly lethal effects of bismuth subnitrate and to reemphasize the method of treatment which may often be an emergency life saving measure.

REPORT OF A CASE

An infant aged 5 weeks and weighing 8½ pounds (3,856 Gm.) was admitted to the medical service of the Children's Hospital with a chief complaint of "blueness" of four hours' duration. The infant's birth and neonatal progress had been uneventful except for short periods of intermittent diarrhea which lasted two to three days. For this difficulty numerous changes of formula had been prescribed. At the time of admission he had been on a formula composed of "Dryco" and water. On the day prior to admission, because of twenty-four hours of fussiness and diarrhea, bismuth subnitrate powder had been prescribed in half-teaspoon doses to be placed in each bottle of formula. Three such feedings were given during the afternoon and evening of the day prior to admission. Eighteen hours after the initial dose the parents noted that the infant's face had become blue and that this hue had rapidly spread over the whole body. This progression was said to have occurred in only a few minutes. At the same time his breathing had become extremely rapid and labored. Physical examination on admission showed that the temperature was 101 F., the pulse rate 184 per minute and the respiratory rate 60. Respiration was deep and typical of air hunger. The skin presented a deep slate-colored cyanosis which involved the entire surface of the body. The heart was observed to be slightly enlarged, and a moderate apical systolic murmur was heard. The remainder of the examination was not noteworthy.

The baby was immediately placed in a Burgess-type oxygen tent with oxygen at high concentration. This procedure diminished the dyspnea but caused no appreciable change in the cyanosis. Blood which was drawn for examination was chocolate colored. The hemoglobin (Sahli) was 10.8 Gm. per hundred cubic centimeters, and the erythrocyte count was 3.3 million per cubic millimeter. On the supposition that fresh hemoglobin would aid the infant, 100 cc. of washed, resuspended red blood cells were infused through a vein of the scalp. This, however, resulted in a decided increase in the cyanosis. While attempts were being made to prepare and administer methylene blue by vein, 50 mg. of methylene blue in 120 cc. of 5 per cent dextrose were given by mouth. Within fifteen minutes the cyanosis had totally disappeared and the infant was breathing normally. No intravenous methylene blue was needed. The initial oral dose was repeated at four hour intervals for three doses, but return of the cyanosis was not observed. The infant was discharged after forty-eight hours and when seen again six days later was thriving. The heart murmur heard on admission had disappeared.

Prior to treatment, blood was drawn into an oxalated tube and stored under oil in the refrigerator. Analysis of this blood[3] after eighteen hours showed 48 per cent methemoglobin. In stored shed blood there is a spontaneous decrease in methemoglobin. The rate of decrease is conditioned by the amount of methemoglobin-forming substances remaining in the blood. In this instance the blood at the time of withdrawal must have contained somewhat more methemoglobin than the analysis revealed. Culture of material from the infant's nose, throat and stool showed no organisms not normally present.

COMMENT

On admission the infant was observed to be critically ill, and a provisional diagnosis of congenital cardiac disease of the potentially cyanotic group was made. The mild cardiac enlargement and heart murmur made this diagnosis seem reasonable. After being placed in the oxygen tent the infant passed a black, watery stool. This, coupled with the chocolate color of the blood, led to the suspicion of methemoglobinemia due to nitrites derived from bismuth subnitrate. More detailed questioning of the parents brought forth the history of medication with a white powder which the dispensing pharmacist stated to be bismuth subnitrate. Because of the emphasis that has been placed on the role of methylene blue in forming methemoglobin to account for the antidotal action of this compound in cyanide poisoning[4] the value of such treatment was not at once realized in this instance. A transfusion of resuspended red cells was given in the hope of increasing the amount of functioning, circulating hemoglobin. The increase in the cyanosis subsequent to this transfusion led to a rapid reconsideration of the pathologic physiology of methemoglobinemia; it became apparent that the newly infused hemoglobin was rapidly converted to methemoglobin, thereby further intensifying the cyanosis. The institution of methylene blue therapy led to the previously noted excellent results.

---

[7] This presence of a common group in these drugs was first called to our attention by Dr. Leo Dickison of the Department of Pharmacology at Vanderbilt University School of Medicine.

[3] Analysis of the blood for methemoglobin was made by Dr. Clement Finch of the Peter Bent Brigham Hospital.

[4] Wendel, W. B.: Methylene Blue, Methemoglobin, and Cyanide Poisoning, J. Pharmacol. & Exper. Therap. **54**: 283 (July) 1935.

It has been shown that under certain circumstances[5] nitrates are reduced to nitrites by the intestinal flora. The absorption of the nitrite so formed results in the conversion by oxidation of the iron in the hemoglobin molecule from the ferrous to the ferric state with the formation of methemoglobin, a non-oxygen-carrying pigment. The kinetics of this reaction have been studied by Darling and Roughton.[6] These investigators have shown that, in addition to the inactivation of a fraction of the oxygen-carrying power of hemoglobin, further physiologic disadvantage occurs because of a decided shift to the left of the oxygen saturation curve of the remainder of the functioning hemoglobin. After a given dose of nitrite there is a spontaneous reconversion of methemoglobin to hemoglobin within eight to nine hours.[7] However, the critical period of anoxia which may lead to death in a few hours warrants the use of methylene blue to hasten the reconversion. Poisoning with nitrites, unlike the methemoglobinemia of so-called enterogenous cyanosis and aniline poisoning, results in a rapid course of events. Physiologically, this is analogous to the effects of rapid hemorrhage versus slow loss of blood. The former is the more likely to end in a lethal occurrence. Ascorbic acid has recently been advocated[8] as superior to methylene blue in the treatment of methemoglobinemia. The effect of ascorbic acid in reversing the equilibrium between methemoglobin and oxyhemoglobin is slow, requiring ten to twelve hours at least, while methylene blue exerts its action in a matter of minutes.[9] In acute poisoning with nitrites death may occur before the antidotal action of ascorbic acid can take place. Ascorbic acid is of value, however, in the treatment of poisoning by such substances as aniline, in which the methemoglobin is continually formed from a given dose over a period of days.

Under certain conditions, as Warburg[10] has shown, methylene blue may form methemoglobin. For this reason its use has been recommended in the treatment of cyanide poisoning by Wendel,[4] and a general belief has become current that its use is contraindicated in methemoglobinemia. Wendel has investigated, in vivo, the clinical action of methylene blue in methemoglobinemia when the drug is used in low concentrations and has thoroughly validated its usefulness. He has advanced the view that the tissues of the body, other than the erythrocytes, rapidly convert methylene blue to the leuko form in which it is a capable reducing agent; the latter form then returns to the erythrocytes to reduce the methemoglobin to hemoglobin.

The toxic effects of methylene blue have been reviewed by Wendel.[7] The effective and safe dosage of the drug is 1 to 2 mg. per kilogram of body weight when given intravenously. The oral dosage is estimated to be approximately ten times the intravenous dose. At such dosage levels toxic effects are not to be expected. The required dose should be given slowly and diluted with 5 per cent dextrose or with isotonic solution of sodium chloride. Paravenous injection is to be avoided. For intravenous use the drug is marketed in a 1 per cent sterile solution in ampules. When the drug is given intravenously the cyanosis generally disappears in fifteen to thirty minutes;[11] with oral dosage the improvement may be delayed several hours. The rapid oral action in the reported case may possibly be attributed to the increased permeability of the gastrointestinal tract associated with diarrhea, in addition to the known rapid turnover of body fluids in the infant. In acute poisoning due to nitrite the wisest course would seem to be the immediate oral administration of methylene blue at a dosage of 10 to 20 mg. per kilogram of body weight to cover the period of obtaining, preparing and administering the drug by the intravenous route. The latter procedure may be time-consuming and not immediately available. Death from anoxia may quickly follow the onset of the cyanosis.

SUMMARY

1. A case of acute methemoglobinemia in a 5 week old infant given bismuth subnitrate for diarrhea is reported.

2. The danger that the administration of bismuth subnitrate may cause methemoglobinemia is stressed.

3. The use and antidotal action of methylene blue in methemoglobinemia is discussed.

[9] Shortly after the admission of the infant whose case is reported herein, a member of the technical staff of the pathology department of the hospital swallowed an unknown amount of sodium nitrite, mistaking it for sodium bicarbonate. Approximately two hours later he became nauseated, felt dizzy and vomited, and intense cyanosis developed. He was unable to move about without syncope. Seventy-five milligrams of methylene blue was given intravenously in a period of five minutes. Before the end of the injection he noted the cessation of a sensation of "drumming" in the ears and relief from a sensation of pressure within the chest. Twenty minutes later he was free from all signs of cyanosis and was able to walk about freely without feeling faint.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

CHORIONIC GONADOTROPIN (See New and Nonofficial Remedies, 1946, p. 470).

The following dosage forms have been accepted:

Lakeside Laboratories, Milwaukee

Choriogonin *(Powder).*

Choriogonin 100 International Units and 500 International Units: 1.5 cc. vials. Vials containing a powdered preparation of chorionic gonadotropin with urea and sodium phosphate which when diluted with the accompanying 1.5 cc. of sterile distilled water, containing 0.5 per cent phenol, provide a solution having a potency of 100 or 500 international units per cubic centimeter.

Choriogonin 1,000 International Units, 5,000 International Units and 10,000 International Units: 10 cc. vials. Vials containing a powdered preparation of chorionic gonadotropin with urea and sodium phosphate which when diluted with the accompanying 10 cc. of sterile distilled water, containing 0.5 per cent phenol, provide a solution having a potency of 1,000 5,000 or 10,000 international units per cubic centimeter.

U. S. trademark 419,102.

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1946, p. 360).

The following article has been accepted:

Julius Schmid, Inc., New York

Ramses Vaginal Jelly: 92 Gm. collapsible tubes. A water soluble jelly formed from carboxymethylcellulose and glycerin having a p_H of 4, prepared from the formula:

Dodecaethylene glycol monolaurate	5.00%
Boric acid	1.00
Alcohol	5.00
Carboxymethylcellulose	2.50
Glycerin	9.00
Butyl parahydroxybenzoate	0.02
Perfume	0.01
Water to make	100.00

Packaged with a Ramses Vaginal Applicator or in refill packages containing a tube of jelly only.

U. S. trademark 306,696.

Ramses Vaginal Applicator: A transparent plastic tube threaded at the blunt intravaginal end to screw onto the tubes of Ramses Jelly to permit filling by compression. A plastic cylinder fitted inside the tube permits the operator to expel the jelly. The full capacity is 5 cc., the recommended dose.

U. S. patents 1,918,706 and 2,077,176.

PENICILLIN TROCHES (See The Journal, March 22, p. 851).

The following dosage form has been accepted:

Bristol Laboratories, Inc., New York

Troches Penicillin Calcium: 1,000 units.

THE TEACHING OF NUTRITION—I

Most physicians are now well aware of the importance of nutrition and believe it should be given greater attention in the teaching of medicine. Since the curriculum is full, however, the proposal does not demand establishment of a new division or the segregation of nutrition in a single department. While the fundamentals of medicine are being taught by the physiologist and the biochemist, the practical application of the science of nutrition may be integrated with the teaching conducted in the clinical branches. Consideration of nutrition is just as important in surgery[1] as in medicine and pediatrics; in obstetrics[2] its importance transcends many other factors.

Pellagra, sprue, beriberi, scurvy and the other deficiency diseases are probably receiving adequate attention, but these disorders are of minor importance compared with the borderline states of nutritive failure. Inadequate nutrition is related to vague ill health and retardation of recovery from many diseases. Recognition of such inadequacies depends not on laboratory technics but rather on the clinical acumen of the physician. Most clinicians have seen the mental depression, lack of initiative and loss of efficiency that accompany nutritive deficiency and the "neurasthenia" in patients who a year later developed frank pellagra.[3] Nutritional neuropathies have been described recently in internees and prisoners of war who lived on grossly deficient diets.[4] Nutrition definitely modifies the course of such diverse diseases as typhoid, peptic ulcer and cirrhosis of the liver.

The student must be taught to recognize these conditions. He must learn to keep in mind the nutritive status when he looks at the patient, at the eyes, the tongue, the gums, the skin and the bony contour. He must remember the importance of nutrition as he tests the reflexes and evaluates nervous stability. He must recognize the heavy draft that infectious and other diseases make on the patient's nutritional resources. He must realize that he can frequently hasten recovery by giving thought to the state of nutrition. If he is interested in the comfort and happiness of those who look to him for advice he must learn that the words adequate and optimum as applied to diet are not synonymous. By giving appropriate advice he can do his part in contributing to the happiness of the patient and ultimately to the improvement of the race.[5]

The Council on Foods and Nutrition emphasizes the importance of a knowledge of nutrition in scientific medicine. The problem, as the Council sees it, is to induce teachers of medicine to weave a heavier design of this relatively new subject into the already tight fabric of daily teaching.

ACQUIRED PENICILLIN RESISTANCE OF TREPONEMA PALLIDUM

The question as to whether or not Treponema pallidum may develop an acquired resistance to penicillin is of clinical and epidemiologic interest. Kolmer and Rule[1] of the Philadelphia Research Institute of Cutaneous Medicine have produced experimental evidence against this acquired tolerance.

In their experiments rabbits were inoculated intratesticularly with the Nichols-Hough strain of T. pallidum. About five weeks later all inoculated rabbits showed acute syphilitic orchitis with strongly positive dark field findings. The minimum curative dose of a commercial penicillin, given in aqueous solution by three intramuscular injections for ten doses, was between 1,000 units per dose, a total dose of 10,000 units per kilogram, and 5,000 units per dose, or a total dose of 50,000 units per kilogram. Rabbits given less than 10,000 units (e. g. a total dose of 4,500 to 9,000 units per kilogram) showed a temporary clinical improvement with negative dark field findings in from seven to fourteen days. This was followed by a relapse with positive dark field findings.

At the end of three weeks a second group of rabbits was inoculated intratesticularly with testicular material from these relapsed animals. All developed acute syphilitic orchitis with positive dark field findings. These animals were then given a subcurative dose of penicillin. All of this group showed clinical improvement with negative dark field findings about seven days after treatment but relapsed clinically about two weeks later. A week later a third group of rabbits was inoculated intratesticularly with material from this second relapsed group. These animals were similarly treated with a subcurative dose of penicillin. The reinoculation was repeated through a fourth group.

[1] Kolmer, J. A., and Rule, Anna M.: Proc. Soc. Exper. Biol. & Med **63**: 240 (Nov.) 1946.

Material from the fourth relapsed group was inoculated into a large fifth group. The minimum curative dose of penicillin was redetermined on this group. Rabbits of this group given a total dose of between 10,000 and 50,000 units per kilogram became permanently negative. The total cure was confirmed by lymph node transfer. Within the limits of the experimental error the results were identical with therapeutic titrations on control rabbits inoculated with the original infectious material. From this Kolmer concludes that T. pallidum does not show evidence of an acquired resistance to penicillin after three consecutive passages through the testicles of rabbits treated with subcurative amounts of commercial penicillin.

This conclusion is in accord with previous conclusions by Tung and Frazer,[2] who found that cultures of T. pallidum did not develop evidence of increased resistance to penicillin after being subjected to fifteen passages through mediums containing substerilizing concentrations of this compound.

PRIMITIVE FAT ORGANS.

Two theories prevail concerning the histogenesis of the fat cell. According to one, it is a cell set apart in early life for the purpose of producing fat, so-called primitive fat "organs" being found in various localities in the form of small groups of stellate or spindle cells richly permeated by capillary vessels. The other theory accounts for the origin of the fat cell on the basis of metaplasia of the fibroblast with accumulation of fat within its body. The fibroblast, when it fails to take on the specialized function of the fat cell, it is assumed, follows its natural inclination and develops into connective tissue. Probably both methods of cellular lipogenesis are effective. In certain pathologic conditions the primordial fat "organs" are increased in size because of hyperplasia of their cellular constituents; inversely, in many cachectic subjects the fat disappears from the cell and the cytoplasm is replaced by serous fluid in the epicardial and perirenal tissues, the cell reverting to the polygonal form of the embryonal unit —so-called serous atrophy of fat. Identical reversionary changes may be produced experimentally in fat tissues by prolonged starvation, but if the animal is given carbohydrate the fat is replaced in the cell body. In the bodies of marantic infants bright cherry-red primitive fat "organs" may sometimes be found in chains or trellis-like formations over such a wide distribution as to resemble a disseminated new growth, especially in intermuscular fascial planes, in the loose connective tissues around the larynx, the esophagus and the thyroid gland, behind the sternum, in the precordial area and around the kidneys. In other circumstances, notably in a wide variety of chronic overproductive inflammatory lesions attended by overgrowth of fibroblasts, the transformation may be observed of young connective tissue elements into cells indistinguishable from those of the primitive fat "organs."

In 1915 Pende[1] described what he believed to be a gland of internal secretion belonging to the endocrine system (glandula insularis cervicalis). He found it in children and in puppies as solid islands of cells which he assumed to be of epithelial nature. However, it is now generally accepted that the structures described by Pende are identical with primitive fat "organs."

The interscapular or hibernating gland of Merkle is a paired fat "organ" which extends over a considerable area in the region of the shoulders and the sides of the neck. It is constant in mammals, and in man it is probably the homologue of the hibernating gland of rodents. Shattock,[2] referring to the hibernating gland of the hedgehog, states that "during hibernation these reserves are used up and dwindle away, a residuum of connective tissue alone remaining, to be again replaced before the arrival of the next hibernating season." Others believe that the fat in these localities is not disturbed during hibernation or starvation. However true this may be, apparently sound opinion holds that the hibernating or interscapular gland is an organ primarily set apart for the storage of fat. The clinical significance of embryonal fat cells is further exemplified in a disease described by Whipple[3] that is characterized by gradual loss of weight and strength, by the presence of abundant neutral fat and fatty acids in the stools and by a variety of fugitive arthritis involving multiple joints. Anatomically, the intestinal villi were enlarged because of extensive deposits in the lymph spaces of neutral fats and fatty acids together with infiltration of the interglandular connective tissues by cells which are morphologically identical with embryonal fat cells. The submucous connective tissues and the mesenteric lymph nodes were similarly affected. Since the appearance of Whipple's paper 7 cases of this description have been reported.[4] Finally, Inglis[5] has described a tumor derived from the polygonal fat cells of the interscapular gland, and Symmers[6] has recorded a spindle and giant cell sarcoma arising presumably from the connective tissues of the intrathoracic primitive fat "organs."

Current Comment

EOSINOPHILIC GRANULOMA OF BONE

In 1940 a granulomatous bone lesion was described by Otani and Ehrlich[1] and by Lichtenstein and Jaffe,[2] who named it eosinophilic granuloma of bone; the disease is now well established under that name. Recently three reports[3] of 10 new cases were published, bringing the number of reported cases to 63, most of them from this country. Consequently the granuloma should be considered in the diagnosis of bone diseases, especially those of localized nature occurring in the early decades of life. Briefly stated, this condition is a more or less self-limited osteolytic, granulomatous process of unknown but possibly infectious nature. In the early stages eosinophilic leukocytes dominate the cellular picture of the lesion; later vacuolated mononuclear cells—foam cells—are more characteristic; healing takes place by fibroblastic proliferation and regeneration of bone. The disease may occur in any part of the skeleton proximal to the wrists and ankles. The lesion, more frequently single than multiple, appears to extend from the marrow Usually the x-rays show a round, oval or irregular area of decreased density and 1 to 4 cm. in diameter. There may be some fever with leukocytosis and also local tenderness, pain and swelling of the soft tissues over the bone lesion. The natural course runs from a few months to a year or more. In single lesions the prognosis seems good even without treatment. Surgical excision, curettage and x-ray treatment have been effective. Most cases appear to heal under the x-rays. Concerning the diagnosis and treatment of eosinophilic granuloma of bone, Dundon, Williams and Laipply[3] say "Because the x-ray appearance of eosinophil granuloma may be indistinguishable from other inflammatory lesions, multiple myeloma or metastatic tumor, a biopsy is usually indicated. Thus, in most cases, the treatment of choice is probably either complete curettage or curettage followed by irradiation." A death from eosinophilic granuloma has not been recorded. Neither have any visceral lesions been described, a curious feature inviting close study. As indicated in the title of the comprehensive paper by Lichtenstein and Jaffe,[4] the mononuclear cells in the intermediate stages of the eosinophilic granuloma suggest a relationship to Letterer-Siwe disease and to the Schüller-Christian syndrome, each associated with a peculiar inflammatory histiocytosis, of which the granuloma may be the mildest clinical manifestation. Dundon, Williams and Laipply mention the occurrence of granuloma in a 17 year old girl; mild symptoms persisted for twenty-eight months and more after the onset, and there was mediastinal lymph node involvement in addition to a lesion of the sternum. Close study of such cases may throw light on the relation of eosinophilic granuloma of bone to extraskeletal and other forms of morphologically similar granulomatous processes.

UVEAL SARCOMAS

A study[1] of 263 cases of uveal sarcomas has revealed that males and females were about equally affected, the average age was approximately 52 years (with a range from 1½ years to 87 years), and people in the sixth decade were most prone to develop the disease. Martin-Jones found few etiologic factors. Although there were many cases in the series with a previous history of trauma, injury was a doubtful predisposing cause. A definite history of trauma was present in 6.4 per cent, an incidence of injury which is in agreement with 8.26 per cent for 1,439 cases of tumors of the eye and orbit observed at the Mayo Clinic. However, the British investigator feels that previous choroidal hemorrhages and old pigmentary changes in the fundus are only occasionally predisposing factors. Abnormal aggregations of pigment both in the choroid and in the iris may undergo malignant transformation. From a clinical diagnostic point of view the majority of the patients in this series presented themselves for examinations with vision reduced to perception of light or complete blindness. Fifty per cent had an increased intraocular tension. Retinal detachment without a "hole" was present in every case. The majority of the tumors were in the posterior part of the globe. Spindle cell tumors were the commonest variety, and epithelioid growths uncommon. Enucleation is, of course, the best treatment. In this series 27 per cent of the patients died within three years of operation, 36 per cent within five years and 56 per cent within ten years. The prognosis was bad in those cases in which melanogen was present in the urine and in patients in whom extraocular extension had taken place.

LOBECTOMY BRINGS LOW MORTALITY

Although the operation of lobectomy has been performed for many years, its value and the low operative mortality of the procedure may not be fully appreciated. Recently, Meade and his colleagues[1] discussed results of 236 lobectomies performed at the Kennedy General Hospital between November 1943 and May 1946. Lobectomy was performed for bronchiectasis, pulmonary cyst, chronic suppuration, bronchial adenoma, adenomatosis, tuberculosis, neurogenic sarcoma and actinomycosis. Bronchiectasis was by far the most common indication. Only 1 patient died. This report offers a splendid illustration of the effectiveness and especially of the safety of lobectomy as performed today.

ORGANIZATION SECTION

Medical Economics

THE TREND TOWARD LABOR HEALTH AND WELFARE PROGRAMS

FRANK G. DICKINSON, Ph.D.
Director of Bureau of Medical Economic Research
Chicago

The health of trade union members has been a subject for union interest ever since 1893. True, extensive health insurance programs as are now being advocated are of comparatively recent development but only as far as they are considered issues related to collective bargaining. Provision for the financial protection of members against wage losses due to illness was among the earliest beneficial activities of trade unions. The barbers, who were organized in 1887, offered sick benefits to their membership in 1893. The tobacco workers and pattern makers provided such benefits as early as 1896. However, the whole history of union sickness benefits has been a troubled one. Many of the plans were begun on an inadequate financial basis. The following is a quotation from a bulletin recently released by the American Federation of Labor regarding the early health benefit plans: "Unions have sponsored their own benefit plans for decades. Often actuarially unsound, and overambitious in scope, many of these plans collapsed."[1] In 1933 twenty unions reported payments of sickness benefits. In 1943 there were eighteen such reports.

What, then, brought about the renewed interest in health and welfare programs, and when did they start their swing into the labor limelight?

The inclusion of health and welfare programs in labor contracts is a wartime development. During the period of the wage stabilization program efforts were made to secure "fringe benefits" in addition to proposed wage increases. The War Labor Board acted kindly toward proposals for sickness pay and approved complete health protection programs if the employer was agreeable; more often than not he was. This gave stimulus to the growth of the plans. Last year a Bureau of Labor Statistics bulletin gave a total of 600,000 as the number of workers covered by collective bargaining agreements which provide for some type of accident or sickness insurance. Just recently Boris Stern, chief of the Industrial Relations Branch of the Bureau of Labor Statistics, estimated that more than a million and a quarter wage earners are covered by agreements which have provisions of that kind.[2] The number is steadily increasing.

In the men's clothing industry 270,000 workers get health benefits. The textile industry covers 150,000; ladies' garment workers 200,000. The laundry, cleaning and dyeing industry covers 30,000. Walter Reuther has just announced a proposal for his 800,000 automobile workers. This is not just a wartime boom. It has real and permanent postwar potentialities.

The aims for inclusion of sick benefit programs within the framework of the collective bargaining agreement are threefold. The American Federation of Labor has announced the advantages of such programs as follows:

> 1. The individual union member is protected against the expenses of unforeseen accidents, sickness and loss of pay—the primary purpose of the program.
>
> 2. The union gains new prestige in the eyes of the old members, prospective members and rival union members. Thus, loyalty is secure from within, expansion made easier and raiding by dual unions made difficult.
>
> 3. The employer will find improved morale and increased cooperation among his employees. Labor turnover is decreased, thus stabilizing the labor force.

With respect to this last advantage, we cannot be certain that all employers will greet the union proposed plans with enthusiasm. In the past many employers sponsored mutual benefit associations as part of an "open shop" device to counteract unionism. Recent employer reaction has ranged from hearty enthusiasm to casual acceptance and, in the case of the coal mine operators, bitter opposition. It is difficult to distinguish between an employer's attitude toward sickness benefits as such and his attitude toward his whole collective bargaining situation. However, the general attitude toward the programs has not been hostile. It will be interesting to watch the response of the automobile manufacturers this spring to Walter Reuther's proposed social security and health benefit program.

The plans which are now in effect have certain general characteristics. First, with respect to benefits provided:

All the benefits are for nonoccupational disabilities. These are (1) weekly cash benefits during periods of illness or of disability caused by accidents, (2) hospital benefits, (3) surgical benefits, (4) maternity benefits and (5) benefits for accidental death, dismemberment and loss of eyesight and (6) several plans which now provide cash benefits for doctors' services.

Many of the plans include weekly disability benefits ranging from 50 to 60 per cent of the employee's regular earnings; other plans provide from $10.50 to $20 a week. Payments for hospital services range from $4 to $5 a day for thirty-one days. Maximum surgical benefits usually range from $100 to $175. A few plans allow specified payments for doctors' services up to a maximum of fifty visits for any one disability. Many programs provide service benefits through the Blue Cross Associated Hospital Service. The general practice has been, however, to provide only cash indemnity payments.

Eligibility requirements for benefits are usually that the worker be employed by a contributing employer and be in good standing in his union. A certain minimum period of employment is usually specified in those plans which are administered by insurance companies.

An important aspect of the programs is the manner in which they are administered. There are three main types of administration: (1) administration by a private insurance company, (2) administration solely by the union and (3) administration jointly by the union and the employer.

Even when the plan is underwritten by a private stock or mutual insurance company, the union and the employers frequently share in the responsibility of administration. A study made and published by the Industrial Relations Section of Princeton University stated that the health and welfare programs now in effect are predominantly union administered. Claims are generally filed through the union office. In some instances benefit payments are made directly by the insurance company. In other plans payments are made through the union office.

In those plans which are to be administered by the insurance company the benefits and coverage are determined through collective bargaining. The employer is then free to contract for such coverage with any company he chooses. It is quite common for the union to have a voice in the day to day administration. Some unions appoint shop committees to adjust individual complaints and grievances and see that the employer is paying the necessary premiums to the insurance company. Some of the unions which already have such plans are C. I. O. and A. F. L. textile workers, American Federation of Hosiery Workers, United Fur and Leather Workers, hotel and restaurant employees and street and electric railway employees.

The union administered benefit plans are financed entirely by the employer or employers who agree to pay a stipulated amount—usually a percentage of the payroll to a benefit fund

---

From the Bureau of Medical Economic Research.

Excerpts from an address before the Annual County Secretaries and Public Relations Conference, Michigan State Medical Society, Detroit, Feb. 2, 1947.

[1] American Federation of Labor; Health Benefit Plans by Collective Bargaining, Collective Bargaining Series No. 1, May 25, 1946.

[2] Stern, Boris: Horizons in Industrial Health and Welfare, J. A. M. A. **132**:760 (Nov. 30) 1946.

established within the union. The International Ladies' Garment Workers Union, the New York City Laundry Workers and the United Hatters, Cap and Millinery Workers all have such plans.

Jointly administered plans are not quite so common. Examples are the Amalgamated Clothing Workers and the United Retail, Wholesale and Department Store Employees. The Amalgamated as far back as 1926 had arrangements whereby union members could receive careful medical examination and advice on health matters.

The great majority of the plans are financed entirely by the employers. The usual method is for the employer to pay a certain percentage of his pay roll. The most elaborate plans are financed by a "tax" or "royalty" on the employer's pay roll or sales revenue, with the union or a joint board of union-employer representatives possessing control over administration of the funds accumulated. Also widely employed is the directly negotiated insurance type plan which lends itself well to contracts covering a small number of employees. Usually the plan requires the employer to secure specific benefits stipulated in the agreement through insurance companies approved by the union, with the employer bearing some or all of the cost. In such cases a fixed pay roll tax is uncommon. Once the specific benefits have been written into the agreement and the insurance company is selected, the administration is no problem.

In bargaining for the pay roll percentage contribution method of financing the benefits, the question of the employer's ability to pay often arises. The unions claim that the fixed pay roll tax is advantageous as a method of employer financing since the costs are more likely to remain constant under this method than they are when the employer selects his own policy and administers the policy stipulated in the labor agreement. The employer who contributes a percentage of his pay roll would not be directly affected by increases in insurance company rates. This advantage, of course, presupposes a constant pay roll—which may or may not be the case.

In the United Mine Workers' Health Fund the agreement provides for a 1.5 per cent pay roll tax which is to be put into one special health fund. Out of this fund will be made payments for illness and disability, the nature of which has not yet been determined. It is not an insurance plan such as has been outlined. In fact, there is no present agreement as to just how any of the money which is to be accumulated in this fund will be distributed. Here is an example of union administration without provision for a private insurance company to underwrite the plan.

There are many problems which must still be faced in the development of union health and welfare programs. There are many types of programs in effect and many new kinds which are being advocated. A single ideal program cannot be evolved to meet equally the needs of different employee groups. Insurance agents have warned the unions that the plans must have a sound actuarial basis or that they will soon disintegrate because of their own inherent weaknesses. Occupation, age and sex of the group must be considered in developing the plan, and problems of administration should be carefully considered.

As far as the relation of the plans to public health insurance is concerned, it is felt that the unions have, at least temporarily, given up the idea of the government providing them with sickness insurance. Walter Reuther has said "There is no evidence to encourage the belief that we may look to Congress for relief. In the immediate future, security will be won for our people only to the extent that the union succeeds in obtaining such security through collective bargaining."[3] The aims of practical "here and now" unionism are being put into effect without waiting for the government to launch any cumbersome compulsory sickness insurance program. Union leaders are fast realizing the practicality of smaller scale plans, geared to their own particular needs, and administered for their own particular interests.

Medical Legislation

STATE LEGISLATION

Colorado

Bill Passed.—H. 895, which passed the senate April 3, proposes to appoint the Colorado State Department of Public Health as the sole agency for carrying out the purpose of the **federal hospital construction act** and to require the governor to appoint a state advisory hospital council.

Delaware

Bill Enacted.—S. 225, which was approved April 5, provides for the establishment of a state **health and welfare clinic** and health center chiefly for children.

Kansas

Bill Passed.—H. 102, which passed the senate April 4, proposes to require all persons applying for a **marriage license** to present a certificate signed by a physician legally qualified under the laws of the state of Kansas or of the state in which he is practicing that the applicant is not infected with syphilis in such a stage as to make it communicable to a marital partner.

Bills Enacted.—H. 67, which was approved April 8, provides for the licensing and **regulating of hospitals** within the state. H. 399, which was approved April 3, is a **hospital survey and construction act** requiring a survey of existing hospital facilities and the preparation of a program for the construction of additional needed facilities. The law also provides for the appointment of an advisory hospital council and authorizes the application for and receipt of federal funds to assist in the survey and construction activities of the state.

Minnesota

Bill Passed.—H. 882, which passed the senate April 9, proposes to prohibit **hospital employees** of a charitable hospital from encouraging, participating in or causing any strike or work stoppage against or directly involving such charitable hospital. A senate floor amendment of April 7 proposes that this restriction should apply also to all state, university, county and municipal hospitals.

New York

Bills Enacted.—S. 740, which has become chapter 422 of the Laws of 1947, amends the revocation provisions of the **medical practice act** by providing that nothing shall prohibit physicians from practicing medicine as partners nor in groups nor from pooling fees and monies received either by the partnerships or groups or by the individual members thereof for professional services furnished by any individual physician, member or employee of such partnership or group, nor shall the physicians constituting the partnerships or groups be prohibited from sharing, dividing or apportioning the fees and monies received by them or by the partnership or group in accordance with a partnership or other agreement. S. 741, which has become chapter 721 of the Laws of 1947, amends the section of the **medical practice act** relating to exemptions by providing that the terms of the act shall not prevent a corporation organized under article nine of the insurance law from employing duly licensed physicians or from entering into contracts with duly licensed physicians or with partnerships or groups of duly licensed physicians to practice medicine on its behalf for persons insured under its contracts or policies.

South Carolina

Bill Passed.—S. 254, which passed the house April 10, proposes to authorize **osteopathic physicians** licensed in the state to certify birth and death certificates in the same manner as is now prescribed by law for other physicians.

Texas

Bill Passed.—H. 217, which passed the house April 9, proposes, among other things, that any physician duly licensed under the laws of Texas to practice medicine who, when an **autopsy** is ordered by a justice of the peace, performs the autopsy in good faith in the belief that the order of the autopsy is a valid order, shall not be held liable for damages in the event it should be determined that the order of autopsy made by the justice of the peace was for any reason invalid.

Coming Medical Meetings

American Medical Association, Atlantic City, June 9-13 Dr George F. Lull, 535 N Dearborn St, Chicago 10, Secretary

Aero Medical Association of the United States, Atlantic City, June 4-6. Dr. David S Brachman, 1016 Dime Bldg, Detroit 26, Secretary

American Association for Thoracic Surgery, St. Louis, May 28-30. Dr. Richard H. Meade Jr, 55 E Washington St, Chicago 2, Secretary.

American Association of Genito-Urinary Surgeons, Absecon, N J, June 4-6 Dr. Charles C Higgins, 2020 E 93d St, Cleveland 6, Secretary

American Association of Industrial Physicians and Surgeons, Buffalo, N Y, Statler Hotel, April 26-May 4 Dr. Frederick W Slobe, 28 E Jackson Blvd, Chicago 4, Secretary

American Association of Pathologists and Bacteriologists, Chicago, May 16-17. Dr Howard T. Karsner, 2085 Adelbert Road, Cleveland 6, Secretary

American Association of Plastic Surgeons, Nashville, Tenn, May 5-6 and Memphis, Tenn, May 7-8 Dr Frederick A Figi, 102 Second Ave S W, Rochester, Minn, Secretary

American Association of the History of Medicine, Cleveland, May 25-26 Dr Howard Dittrick, 2020 E 93d St, Cleveland 6, Secretary.

American Association on Mental Deficiency, St Paul, Minn, May 28-31. Dr Neil A Dayton, Box 51, Mansfield Depot, Conn, Secretary

American College of Allergists, Atlantic City, Hotel Senator, June 6-8 Dr Fred W Wittich, 401 LaSalle Medical Bldg, Minneapolis 2, Secretary

American College of Chest Physicians Atlantic City, June 5-8 Mr Murray Kornfeld 500 N Dearborn St, Chicago 10, Executive Secretary

American College of Physicians, Chicago April 28-May 2. Mr. E R Loveland, 4200 Pine St, Philadelphia 4, Secretary

American College of Radiology, Atlantic City, June 7-8 Mr Mac F. Cahal, 20 N Wacker Drive, Chicago 6 Executive Secretary

American Dermatological Association, Murray Bay, Quebec Can, June 1-5. Dr Harry R Foerster, 208 E Wisconsin Ave, Milwaukee, Wis, Secretary

American Federation for Clinical Research, Chicago, Hotel Sherman, April 28 Dr Richard H Lyons, University Hospital, Ann Arbor, Mich, Secretary

American Geriatrics Society, Atlantic City, Hotel Brighton, June 5-7. Dr Malford W. Thewlis, 25 Mechanic St, Wakefield, R. I., Secretary

American Heart Association, Atlantic City, Hotel President, June 6-7. Dr. Howard B Sprague, 50 W. 50th St, New York, Secretary

American Medical Women's Association, Atlantic City, June 7-8 Dr. Helen F. Schrack, 216 N Fifth St, Camden, N J, Secretary.

American Neisserian Medical Society, Atlantic City, Marlborough Blenheim Hotel, June 8 Dr William L Fleming, 750 Harrison Ave, Boston, Secretary

American Neurological Association, Atlantic City, Ambassador Hotel, June 16-18 Dr Walter O. Klingman, 195 Ft. Washington Ave, New York 32, Secretary

American Ophthalmological Society, Hot Springs, Va, June 5-7 Dr. Walter S Atkinson, 129 Clinton St, Watertown, N. Y, Secretary.

American Pediatric Society Stockbridge, Mass, May 13-15. Dr. Henry G Poncher, 1819 W Polk St, Chicago 12, Secretary.

American Physiological Society, Chicago, May 18-22. Dr. Maurice Visscher, University of Minnesota, Minneapolis, Secretary.

American Proctologic Society, Atlantic City, June 7-8 Dr. Harry E. Bacon, 2031 Locust St, Philadelphia 3, Secretary.

American Psychiatric Association, New York, Hotel Pennsylvania, May 19-23. Dr. Leo H Bartemeier, General Motors Bldg, Detroit, Secretary.

American Radium Society, Atlantic City, June 8 Dr Hugh F. Hare, 605 Commonwealth Ave, Boston 15, Secretary.

American Society for Clinical Investigation, Atlantic City, Chalfonte Haddon Hall, May 5 Dr Eugene A Stead Jr, Grady Hospital Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Chicago, May 19-23 Dr. Frieda S Robscheit Robbins, 260 Crittenden Blvd, Rochester, N. Y, Secretary

American Society for Pharmacology and Experimental Therapeutics, Chicago, May 18-22 Dr Harvey B Haag, Medical College of Virginia, Richmond 19, Va, Secretary

American Society for Research in Psychosomatic Problems, Atlantic City, May 3-4 Dr Edwin G Zabriskie, 714 Madison Ave, New York 21, Secretary.

American Society for the Study of Sterility, Atlantic City, Hotel Shand, June 7-8 Dr John O Haman, 490 Post St, San Francisco 2, Secretary.

American Society of Biological Chemists, Chicago, May 18-22 Dr. Otto A. Bessey, Public Health Research Institute, New York 9, Secretary.

American Society of Clinical Pathologists, Atlantic City, June 4-8 Dr. Alfred S Giordano, 531 N Main St, South Bend, Ind, Secretary

American Society of Electroencephalography, Atlantic City, Marlborough Blenheim Hotel, June 13-14 Dr. Robert S Schwab, Massachusetts General Hospital, Boston 14, Secretary

American Therapeutic Society, Atlantic City, Chalfonte Hotel, June 6-7. Dr. Oscar B Hunter, 1835 I St, N W., Washington 6, D C, Secretary.

Arizona State Medical Association, Tucson, May 7-10. Dr. Frank J Milloy, 112 N. Central Ave, Phoenix, Secretary.

Association for the Study of Internal Secretions, Atlantic City, June 6-7. Dr Henry H. Turner, 1200 N Walker St, Oklahoma City 3, Secretary.

Association of American Physicians, Atlantic City, May 6-7. Dr. Joseph T. Wearn, Lakeside Hospital, Cleveland 6, Secretary.

California Medical Association, Los Angeles, Hotel Biltmore, April 30-May 3 Dr. L Henry Garland, 450 Sutter St, San Francisco 8, Secretary.

Connecticut State Medical Society, New Haven, April 28-30 Dr. Creighton Barker, 258 Church St, New Haven 10, Secretary.

Federation of American Societies for Experimental Biology, Chicago, May 18-22 Dr William H. Chambers, 1300 York Ave, New York 21, Secretary.

Hawaii Territorial Medical Association, Lihue, Kauai, May 1-4 Dr. Harry L. Arnold Jr., 510 S Beretania St, Honolulu 53, Secretary.

Idaho State Medical Association, Sun Valley, June 16-19 Dr. William B Handford, Caldwell, Secretary

Illinois State Medical Society, Chicago, Palmer House, May 12-14 Dr. Harold M Camp, 224 S. Main St, Monmouth, Secretary.

Kansas Medical Society, Topeka May 12-15 Dr John M Porter, 512 New England Bldg, Topeka, Secretary.

Louisiana-Mississippi Ophthalmological and Otolaryngological Society, Biloxi, Miss, Buena Vista Hotel, May 5 Dr Edley H Jones, 1301 Washington St, Vicksburg, Miss, Secretary

Louisiana State Medical Society, New Orleans, May 12-14 Dr P. T. Talbot, 1430 Tulane Ave, New Orleans 13, Secretary.

Massachusetts Medical Society, Boston, Hotel Statler, May 20-22 Mr. Robert St B Boyd, 8 Fenway, Boston 15, Executive Secretary

Medical Library Association, Cleveland, Wade Park Manor, May 27-29 Miss Heath Babcock New York State Medical Library, Albany 1, New York, Secretary

Mississippi State Medical Association, Biloxi, May 6-8 Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

National Gastroenterological Association, Atlantic City, June 4-6 Dr. G. Randolph Manning, Room 319, 1819 Broadway, New York, Secretary.

National Tuberculosis Association, San Francisco, June 16-19 Dr F. D Hopkins, 1790 Broadway, New York 19, Executive Secretary

Nebraska State Medical Association, Omaha, April 28-May 1. Dr R. B Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New Mexico Medical Society, Albuquerque, April 30-May 3 Dr. H. L. January, 221 West Central Ave, Albuquerque, Secretary

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19-20 Dr. Carleton R Metcalf, 5 South State Street, Concord, Secretary.

New York, Medical Society of the State of, Buffalo, May 5-9 Dr. Walter P. Anderton, 292 Madison Avenue, New York 19, Secretary.

North Carolina, Medical Society of the State of, Virginia Beach, Va, Cavalier Hotel, May 12-14. Dr. Roscoe D McMillan, P. O. Box 232, Red Springs, Secretary.

North Dakota State Medical Association, Fargo, May 25-27. Dr. L. W. Larson, 221 Fifth St, Bismarck, Secretary.

Ohio State Medical Association, Cleveland, May 6-8 Mr Charles S. Nelson, 79 E State St, Columbus 15, Executive Secretary

Oklahoma State Medical Association, Tulsa, Mayo Hotel, May 14-16. Mr R H. Graham, 210 Plaza Court Bldg, Oklahoma City, Executive Secretary.

Rhode Island Medical Society, Providence, May 14-15. Dr. Morgan Cutts, 106 Francis St, Providence 3, Secretary.

Society of American Bacteriologists, Philadelphia, May 13-16 Dr. Leland W Parr, 1335 H St N W, Washington 5, D. C., Secretary.

South Dakota State Medical Association, Rapid City, May 31-June 3. Dr. Roland G. Mayer, 22½ S Main St, Aberdeen, Secretary.

Texas, State Medical Association of, Dallas, Adolphus Hotel, May 5-8 Dr Holman Taylor, 1404 W. El Paso St, Fort Worth 3, Secretary.

United States-Mexico Border Public Health Association, San Diego, California, and Tijuana, Mexico, May 6-8 Dr James A. Grider Jr., 151 U. S Court House, El Paso, Texas, Secretary.

West Virginia Medical Association, Charleston, May 12-14 Mr. Charles Lively, 1031 Quarrier St, Charleston 24, Secretary.

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Colonel John Hargreaves

Col. John Hargreaves, M. C., U. S. Army, has been awarded the Bronze Star Medal and the Legion of Merit for meritorious achievement in connection with military operations against the enemy on Okinawa from Aug. 24, 1945 to Jan. 9, 1946. As surgeon, Eighth Air Force, he exhibited superior professional competence and sound judgment in solving numerous complex problems incident to the organization and direction of an effective medical service for that command. He inaugurated and supervised efficient field sanitary measures which resulted in an extremely low disease incidence rate despite adverse living conditions. Through his ability, resourcefulness and devotion to duty Colonel Hargreaves made a vital contribution to the success of the mission of the Eighth Air Force.

Selected also for citation were his services from July 1942 to July 1945 as surgeon Air Service Command and surgeon Air Technical Service Command. He directed most successfully the Industrial Medical Program and specialized training and classification of medical officer personnel for the Air Forces. His professional knowledge, presight and energetic effort contributed immeasurably to the success of this difficult program. Dr. Hargreaves graduated from the University of Minnesota Medical School in 1924 and entered the military service in 1924.

Lieutenant Colonel Francis E. McDonough

The Legion of Merit has been awarded to Lieut. Col. Francis E. McDonough, M. C., A. U. S., of Boston, who was cited for exceptionally meritorious conduct in the performance of services from Jan. 1, 1944 to Aug. 15, 1945. As assistant air surgeon of the XX Bomber Command, he ably and loyally supported the surgeon in guarding and maintaining the health of Bomber Command personnel in India and China, a task complicated by dispersal of bases over thousands of miles of territory with varying climatic and endemic disease problems. Lieutenant Colonel McDonough spent long hours at unusually hard work finding solutions to these problems. As wing surgeon of the 58th Bombardment Wing he planned the entire medical program for more than 10,000 officers and enlisted men. On arrival at Tinian he designed and followed through on the construction of a consolidated wing dispensary. His thorough knowledge of internal medicine, his appreciation of the flight surgeon's problems, his cooperative attitude and his unusual fidelity have made his services during the entire period of outstanding value. Dr. McDonough graduated from the University of Wisconsin Medical School in 1934 and entered the military service July 7, 1942.

Colonel John M. Murray

The Legion of Merit has been awarded to Col. John M. Murray (then Lieut. Col.), M. C., A. U. S., of Boston, the citation reading "As chief of the psychiatric branch, Office of the Air Surgeon, during the period from January 1943 to October 1944, Colonel Murray displayed extraordinary foresight and professional skill in successfully completing the organization of psychiatric service of the Army Air Forces. His outstanding achievement in the establishment of schools for the indoctrination of medical officers in modern psychiatric methods reflects great credit on himself and on the military service." Dr. Murray graduated from the University of Pennsylvania Medical School in 1921 and entered the military service, Nov. 1, 1942.

Lieutenant Colonel Willard H. Waterous

The Legion of Merit has been awarded to Lieut. Col. Willard H. Waterous, M. C., A. U. S., of Manila, P. I., for his services as chief of the eye, ear, nose and throat service at General Hospital Number 2, Bataan, Philippine Islands, from December 1941 to May 1942. Despite the lack of medications and equipment, the citation recalls that he successfully performed many difficult operations, and throughout the final days of the defense of the Bataan Peninsula he continued to exercise his characteristic cheerfulness and optimistic demeanor to such a degree as to enhance the morale and well being of all with whom he came in contact. His conduct reflects credit on himself and on the military service.

Dr. Waterous has also been awarded the Bronze Star Medal and the Oakleaf Cluster in lieu of a second Bronze Star Medal. He was a prisoner of the Japanese from April 9, 1942 until released by the American forces Feb. 5, 1945. He graduated from Northwestern University Medical School in 1916 and entered the service Dec. 11, 1941. Since the war Dr. Waterous has conducted a medical clinic in Manila.

Lieutenant Colonel Howard D. Fabing

The Legion of Merit has been awarded to Lieut. Col. Howard D. Fabing (then Major), M. C., A. U. S., of Cincinnati, for exceptionally meritorious conduct in the performance of outstanding services as director of the School of Military Neuropsychiatry, 312th Station Hospital, European Theater of Operations, from Nov. 15, 1943 to June 30, 1944. The citation reads, in part, that Major Fabing supervised the various courses and did all the teaching of division medical officers at the school. Through his efforts the training film entitled "Combat Exhaustion" was produced. He standardized therapy for the treatment of front line neuropsychiatric casualties so that over half of the men suffering from this disturbance could be returned to duty within a week. Few of the men who attended the school had previous special training in psychiatry, but, employing the methodology taught by Major Fabing, they have been successful in treating psychiatric casualties in the combat zones. Dr. Fabing graduated from the University of Cincinnati College of Medicine in 1932 and entered the military service Dec. 30, 1942.

Major Nathan B. Friedman

The Army Commendation Ribbon has been awarded to Major Nathan B. Friedman (then captain), M. C., A. U. S., who served from July 31, 1942 to Jan. 23, 1946, and whose intelligence and application to duty says the citation, contributed in large measure to the professional success of the Army Institute of Pathology, especially as it concerned diseases of the genitourinary tract and of the endocrine glands. His studies and research have contributed materially to medical knowledge, particularly of tumors of the testis and to the pathology of injuries resulting from cold and immersion, all conditions of great importance to the military service. Dr. Friedman graduated from Cornell University Medical College, New York, in 1934 and entered the military service July 30, 1942.

Captain Morris A. Shapiro

The Silver Star and the Oak Leaf Cluster to the Silver Star were awarded to Capt. Morris Shapiro, M. C., A. U. S., of Schenectady, N. Y., for gallantry in action in the vicinity of El Guettar, Tunisia, March 23, 1943. One notes from the citation that, when a medical detachment had been immobilized by enemy artillery fire, Captain Shapiro organized a group of soldiers as litter bearers and throughout several hours of concentrated enemy artillery fire directed the successful evacuation of the wounded.

His gallantry in action in the vicinity of St. Cloud, Algeria, Nov. 9, 1942, is also cited. When all other attempts had failed, Captain Shapiro, at grave risk to his own life, crept forward beyond our front lines and evacuated a seriously wounded officer who was lying exposed to constant enemy shell and small arms fire. His exemplary conduct inspired the members of his battalion. Dr. Shapiro graduated from Albany Medical College in 1936 and entered the service Feb. 17, 1941.

VETERANS ADMINISTRATION

LONG RANGE MEDICAL RESEARCH PROGRAM

Out of a conference called in April 1946 by the National Research Council at the suggestion of the Surgeon General of the Army is developing a long range program of medical research to improve the medical care of veterans. Some of the nation's foremost medical groups, the Army, Navy and Public Health Service are cooperating in this program. The conference stressed that the wealth of medical information accumulated by the armed forces during the war could be the starting point for clinical studies from which would come the best possible medical care for veterans in the years ahead. Then a committee of the National Research Council (Dr. Edward D. Churchill, chairman) outlined a broad program, and the chairman, Division of Medical Sciences, National Research Council (Dr. Lewis H. Weed), appointed a committee to handle details of the research program. As it develops the program is expected to include (1) follow-up studies to further knowledge of the natural history of diseases and the results of treatment, (2) clinical studies to be carried out in VA hospitals and other institutions and (3) statistical studies on mortality, morbidity and continued disability. Physicians of the Army, Navy and Veterans Administration desiring to submit proposals for research projects may do so on special forms provided for those agencies. All others may obtain forms from the office of the committee on Veterans Medical Programs, 2101 Constitution Avenue, Washington, D. C. The following doctors are on the committee:

O. H. Perry Pepper, Philadelphia.
Francis J. Braceland Rochester, Minn.
Edward D. Churchill, Boston.
Winchell McK. Craig Minneapolis.
Michael E. DeBakey, New Orleans.
Louis I. Dublin, New York.
Morris Fishbein, Chicago.
Perrin H. Long, Baltimore.
William C. Menninger, Topeka, Kan.
J. Roscoe Miller, Chicago.
Hugh J. Morgan, Nashville, Tenn.
Cornelius P. Rhoads, New York.
Milton C. Winternitz, New Haven, Conn.

ADVANCED TRAINING FOR NURSES

The Veterans Administration is conducting advanced courses in neurologic, psychiatric and tuberculosis nursing. Classes in neurologic nursing held at the VA hospital in Hines, Ill., for three months ended March 16 placed special emphasis on the care of paraplegic patients. The course, to be repeated in April, carries credit points of ten semester hours from DePaul University, Chicago. The course in advanced psychiatric nursing at the University of Minnesota, Minneapolis, which ended April 3, carries fifteen college credit hours. This course is being repeated beginning March 29. Advanced instruction in the care of tuberculous patients is being held at the VA hospital in Oteen, N. C. Classes, which began February 1, will extend through May 1. A course to teach VA nurses methods of training neuropsychiatric attendants was held in January at Cushing General Hospital, Framingham, Mass. A total of 113 nurses so far have attended the courses.

NEW HOSPITAL MANAGERS

Dr. Frank C. Cassidy, manager of the Veterans Administration hospital, Outwood, Ky., was appointed manager of the VA hospital, Memphis, Tenn., effective March 23. Dr. Raymond E. Scott, San Antonio, Texas, will succeed Dr. Cassidy at Outwood, Ky. Dr. Scott, a veteran of both world wars, during World War II was chief of laboratory service at Fort Bliss, Texas, and later served in this country and in Africa and Europe as inspector and instructor in army hospitals and as commanding officer of the 11th Evacuation Hospital. Dr. Cassidy, a graduate of Tufts College Medical School, has been in service in veterans' hospitals for many years.

Dr. Paul C. Bruce, a veteran of both world wars, is now manager of the VA hospital, San Fernando, Calif., succeeding the late Dr. Samuel H. James. Dr. Bruce formerly was manager of the VA hospital at Legion, Texas.

PUBLIC HEALTH SERVICE

HEADQUARTERS MOVED TO SOCIAL SECURITY BUILDING

The headquarters for the U. S. Public Health Service, formerly 1901 Constitution Avenue N.W., is now in the Social Security Building, Fourth Street and Independence Avenue S.W., Washington, D. C. The Public Health Service units now located in the Social Security Building are those which are part of the Office of the Surgeon General. They are the division of commissioned officers, the dental division, the sanitary engineering division, the division of nursing and the division of public health methods. Also included are the office of international health relations, the budget and fiscal office and employment office and office of the chief clerk in the office of the executive assistant.

The Public Health Service building on Constitution Avenue will be occupied by the Atomic Energy Commission. The Public Health Service headquarters have been in this building since 1933 with the exception of a period during the war when it was occupied by the joint chiefs of staff and the combined chiefs of staff.

OFFICERS RELEASED FROM SERVICE

U. S. Public Health Service headquarters reports that the following medical officers have been terminated, inactivated or retired and directed to proceed to the city opposite their name:

Buck, Irvin F., assistant dental surgeon (R), Saint Cloud, Florida.

Casey, Harry E., engineer (R), Whitehouse, Ohio.

Hinson, Harry L., J. A. sanitarian (R), Charlotte, N. C.

Kaniss, Harry A., S. A. dental surgeon (R), Reading, Pa.

Lentz, Phyllis S., J. A. nurse officer (R), Mobridge, S. D.

HEALTH EDUCATION

Dr. Mayhew Derryberry, chief U. S. Public Health Service's office of health education, has been assigned temporarily as consultant in health education with the American National Red Cross. Dr. Derryberry, at the request of the Red Cross, will study its present health education services for the purpose of evaluating and coordinating programs now in operation and will advise with Dr. G. Foard McGinnes, Red Cross vice chairman for health services, on possible future health education activities of the national organization.

MEDICAL RESEARCH GRANTS

The National Advisory Health Council has recommended medical research grants amounting to more than $2,000,000. These grants must first be approved by the Surgeon General, Dr. Thomas Parran, and then are contingent on appropriations by Congress for the fiscal year which begins July 1. Of the 193 grants that supplement existing funds of universities and other research institutions, the largest, $105,800, was recommended for a study of syphilis by the Pan American Sanitary Bureau. Sums of $52,454 and $46,000 respectively were slated for the study of malaria by the University of Chicago and Christ Hospital, Cincinnati. Six other grants were above $30,000. An additional 55 grants were favorably considered but await modification of the amount or further study by the research grants division of the National Institute of Health before final action is taken. The research study involved in these grants covers a diverse number of subjects. The use of grants in aid in pursuing these studies implies no degree of federal control. The National Advisory Health Council which recommends research grants consists of fourteen members ten of whom are experts not otherwise employed by the government (THE JOURNAL, March 15, p. 790).

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

CALIFORNIA

Personal.—Dr. James J. Short, for many years associated with the New York Post-Graduate Medical School and Hospital, Columbia University, New York, is now on the faculty of the College of Medical Evangelists, Loma Linda-Los Angeles, as associate professor of medicine.——Dr. Leo Eloesser, San Francisco, for two years in charge of the medical teaching program for China under UNRRA, discussed his experiences in China before the Institute of Pacific Relations and the California League of Women Voters March 4.——Dr. C. S. Ambrose, Visalia, has been appointed health officer of Tulare County to succeed Dr. Charles C. Hedges.——Dr. Donald L. Meamber, recently returned from service in the Pacific theater with the Navy, has been appointed health officer of the city of Yreka.——Dr. Jacob M. Furstman, for twenty-four years chief administrative head of the Monrovia Health District, Monrovia, became health director of the Santa Monica District Health Office March 1, succeeding Dr. William F. Reasner, Santa Monica, who is retiring from county service.——Dr. Herbert L. Herschensohn, Santa Monica, has been appointed medical director for the Douglas Aircraft Company. Dr. Herschensohn, a graduate of New York University Medical School, is the author of a series of articles entitled "The Germs We Live With," published by *Hygeia*, the Health Magazine.

Changes in Licensure.—The Board of Medical Examiners meeting March 10 made the following changes in the status of licentiates: Frederick S. Lorenz, Beverly Hills, was found guilty of unprofessional conduct and his license was revoked. The order of revocation was suspended for five years, and he was placed on probation with specified terms for the period. The license of Dr. David A. Stevens, Lynwood, was revoked when he was found guilty of unprofessional conduct. Dr. Leonard D. Wood, Laguna Beach, was found guilty of unprofessional conduct; his license was suspended for one year and he was placed on probation for ten years without narcotics. The license of Dr. Jean Andrews was restored and the doctor was placed on probation for five years without narcotics. License was restored to Dr. Wendell W. White, Los Angeles, and he was placed on probation for a period of five years with specified terms.

Kern County Hospital Investigation.—A legislative subcommittee which has been investigating the administration of the county operated Kern General Hospital in Bakersfield has recommended the enactment of a law requiring such institutions to obtain licenses from the state department of public health. The subcommittee, headed by C. Don Field of Los Angeles County, filed a fifty-three page report charging the Kern County Hospital with employing unlicensed doctors, one of whom was accused of selling donated blood and retaining the proceeds. Chairman Field said a copy of the report is being forwarded to the attorney general for "proper action." "It is incredible and amazing," the report said, "that a situation such as that disclosed by the evidence at the subcommittee's hearings could have existed in Kern County; that a score of unlicensed doctors would be hired as county employees, with the knowledge of the board of supervisors and of the medical director of the county hospital and be permitted to practice medicine in flagrant violation of our law." The report noted that the Kern County district attorney has filed charges against Dr. Alfred E. Rhoden, Bakersfield, accused of practicing without a California license, and that the state board of medical examiners has suspended for one year the license of Dr. Nicolai N. Rilcoff, Bakersfield, former medical director of the hospital, after which he will be placed on probation for a period of five years (Sacramento, Calif., *Bee*, March 31, 1947).

COLORADO

Personal.—Dr. Horace J. Dodge, former director of public health at Coeur d'Alene, Idaho, has joined the faculty of the University of Colorado School of Medicine as assistant professor of public health and preventive medicine. After receiving his M.D. at the University of Colorado and taking his internship and residency at Colorado General Hospital, Dr. Dodge obtained his master's degree in public health at the University of Michigan.

Grant to Study Tick Fever.—Lederle Laboratories has renewed its grant of $2,400 to the University of Colorado School of Medicine, Denver, for continuing research on Colorado tick fever. Under the direction of Dr. Lloyd J. Florio, professor of public health and laboratory diagnosis, studies will be continued to try to determine how the disease is spread, whether it exists in other areas and whether the virus can be isolated in nature.

Hospital Classroom for Children.—A playroom and classroom for children undergoing treatment at Colorado General Hospital, Denver, have been built and furnished at the hospital in memory of a former Denver teacher, Lillian Drayton Matheson. The rooms were made possible by remodeling the south porch of the children's ward in the hospital. Attractively decorated and furnished for children, the classroom contains necessary schoolroom equipment, and the board of education supplies the services of a full time teacher.

University Medical Center.—Dr. Ward A. Darley Jr., dean, University of Colorado School of Medicine, Denver, has been named director of the University of Colorado Medical Center. The medical center is the new name approved by the University Board of Regents for the schools of medicine and nursing, Colorado General Hospital and the Colorado Psychopathic Hospital located in Denver. Dr. Darley's new title as director of the medical center entails no new duties, as he has been serving as the director of the schools and hospitals with the title as dean of the school of medicine, a position he will continue to hold.

CONNECTICUT

Studies of State Society Objectives.—Dr. Courtney C. Bishop, New Haven, was elected chairman and Dr. Frank H. Couch, Cromwell, secretary of the Committee to Study the Organization and Objectives of the State Medical Society at its recent meeting in New Haven. The committee, authorized by the House of Delegates last December, is composed of one council member and one additional delegate from each of the eight component county medical associations. It will meet once a month.

DISTRICT OF COLUMBIA

Appointments at Georgetown University.—Dr. Norman Q. Brill, assistant chief, neuropsychiatry, Veterans Administration, has been named professor of neurology and director of the department. Dr. Brill, a graduate of New York University College of Medicine, New York City, has served on the staffs of Montefiore Hospital for Chronic Diseases and Mount Sinai, Morrisania City, New York Postgraduate and Sydenham hospitals in New York City. He was also an instructor in neurology at Columbia University College of Physicians and Surgeons, New York City. He received his M.D. degree from Johns Hopkins University School of Medicine, Baltimore, in 1928. Dr. Willi Baensch, newly named professor of roentgenology, recently came to this country from the University of Leipzig. At the last meeting of the International Congress of Radiology in Chicago in 1937 he was elected secretary general of the organization. Dr. Samuel P. Hicks, a graduate of the University of Pennsylvania School of Medicine, Philadelphia, has been named associate professor of pathology. During the war he was in charge of the laboratory, base hospital No. 17, in New Guinea and has been assistant pathologist and head of the department of pathology, Naval Medical School, Naval Medical Center, Bethesda, Md. Dr. Robert F. Dow, Bethesda, Md., has been appointed head of the department of physical therapy. Dr. Dow in 1939 became director of the physical and fever therapy department at St. Joseph's Hospital, Paterson, N. J. Following military service he was appointed chief of physical medicine and physician-in-chief, medical rehabilitation, of the Veterans Administration Hospital, Washington, D. C.

ILLINOIS

Personal.—Dr. P. Kenneth Gieser, eye specialist, Wheaton, left last month for Kano, Nigeria, West Africa, to take charge of an eye hospital. Dr. Gieser graduated from Northwestern University Medical School, Chicago, and had additional training at the Illinois Eye and Ear Infirmary in Chicago.

Moorehead Memorial Fund.—A committee to plan a suitable memorial to the late Frederick B. Moorehead, D.D.S., M.D., former dean of the College of Dentistry, University of Illinois, Chicago, has been created by the Alumni Association of the college. The alumni and friends of Dr. Moorehead in the medical and dental professions are asked to send their checks to Robert I. Humphrey, D.D.S., Treasurer, Moorehead Memorial Committee, 185 North Wabash Avenue, Chicago.

Construct Plant to Eliminate River Pollution.—A recovery plant to eliminate all pollution in the Illinois River caused by the discharge of residues at the American Distilling Company's Pekin plant is being constructed and is expected to be in operation next summer. It will recover wastes equivalent to the average domestic wastes from a city of about 575,000 persons and is the final step in the pollution abatement program of the company cooperating with the state water board.

Physical Examination of School Children.—Illinois school children will be given physical examinations beginning Child Health Week, May 4-10, to be completed some time before the September opening of the schools, the Illinois State Medical Society announced April 6. The examinations are a part of the state law passed in June 1945 requiring, "as soon as practicable," that examinations be made of school children in all public, elementary and secondary schools at the time they enter first grade and again in not less than every fourth year thereafter. The exceptions are children whose parents object on religious scruples. Examinations will be made individually or in groups by appointment in the offices of physicians or in some communities at the schools.

Cook County Mosquitoes.—The Advisory Committee of the Chicago-Cook County Health Survey recommended an expanded attack on the mosquito population of Chicago and Cook County. The report was prepared by the United States Public Health Service as part of an audit of health conditions asked by city and county officials. The Des Plaines Valley and the North Shore Mosquito Abatement district, which began operation in 1928, are the only anti-mosquito agencies in the county. Using figures from a federal Works Progress Administration survey of the mosquito problem in 1940, the report disclosed that, of the estimated 66,698,000,000 mosquitoes in the county as a whole, 24 per cent, or 16,000,000,000 were produced in Chicago within Lake, Hyde Park and Calumet townships. If the seven southern townships within the county—Palos, Worth, Orland, Bremen, Thornton, Rich and Bloom—are added, "we find that 48 per cent of the breeding places within the county are within these ten southern townships and 49.6 per cent of mosquito production occurs therein." The report suggested enlargement of the Des Plaines Valley Abatement District to include the southern section and formation of new abatement districts in other parts of the county if necessary. The Des Plaines district has a permanent staff of ten, which is tripled during the mosquito season, and it annually spends about $45,000 on construction work, such as ditching, and on maintenance and control measures. The North Shore district has a similar staff. The most important two types of mosquitoes from the pest standpoint are Culex pipiens and Aedes vexans. The former breed in water collections near human habitations and are vicious biters both indoors and out. Aedes vexans rarely goes inside habitations and is particularly troublesome on porches, in yards and in recreational areas during the summer. It deposits eggs in dry depressions, and they hatch when the depressions become flooded. They resist winter temperatures and produce early spring broods. Two forms of Anopheles are found in the Cook County area but not in sufficient quantities to be of any great health hazards. The report adds, however, "it should always be borne in mind that, where Anopheles quadrimaculatus is prevalent and where persons infected with malaria come into the area there is always the possibility of a flare-up in that disease."

Chicago

The Bacon Lecture.—Hermann J. Muller, Ph.D., professor of zoology at Indiana University, will deliver the 1947 Charles Sumner Bacon lecture at the University of Illinois professional colleges, Wood and Polk streets, at 1 p. m. May 28 on "Human Erosion by Mutation." It is being sponsored by the department of obstetrics and gynecology.

The Joseph Capps Prize.—The Institute of Medicine of Chicago is again offering the Joseph Capps Prize of $400 for the most meritorious investigation in medicine or its specialties or in the fundamental sciences, provided the work has definite bearing on some medical problem. Competition is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1945 or thereafter. Manuscripts must be submitted to the secretary of the Institute of Medicine of Chicago, 86 East Randolph Street, Chicago 1, not later than December 31.

Northwestern University Medical Center.—Another step toward the $100,000,000 medical center now being established on the Chicago campus of Northwestern University Medical School was taken April 9 when Dr. J. Roscoe Miller, dean, announced receipt of the first of several gifts expected to total more than $5,000,000 for the creation of a fund to facilitate expanded research in the field of venereal diseases, other public health problems and medical education. The initial gift of $190,172, with others to follow in succeeding months, has been made from assets of the Public Health Institute of Chicago, founded in 1920 and supported by a large group of Chicago business men, which ceased operation early this year. Both the principal and the income from the half million dollar fund will be employed for research as well as for treatment and examination of patients in the clinic. Equipment and other physical property of the institute are to be turned over to the university to be used in connection with the fund. Erection of a neuropsychiatric hospital is assured through a bequest of a million and a half dollars from the late Mrs. Joy Morton. The Veterans Administration soon will build on the Chicago campus a 600 bed cancer hospital for the study and treatment of cancer. Mercy Hospital has purchased land adjacent to the campus on which it will erect a $10,000,000 hospital. Other hospitals, now located in various parts of Chicago, likewise are planning to move to or near the Chicago campus.

IOWA

Course in Audiometry.—The State University of Iowa will again offer an intensive four weeks course in audiometry and the fitting of hearing aids under the department of speech, psychology and otolaryngology from June 23 to July 19. A series of week end lectures and round table discussions on various aspects of hearing conservation will be part of the summer program. The speakers will be Mrs. Spencer Tracy, director of the John Tracy Clinic, Los Angeles; Dr. Helen Lane, principal, Central Institute for the Deaf, St. Louis; Dr. Werner Mueller, associate in otolaryngology, Massachusetts Eye and Ear Infirmary, Boston, and Harvard Medical School, and Martin F. Palmer, Sc.D., director, Institute of Logopedics, the Municipal University of Wichita, Kan. Inquiries may be addressed to Jacqueline Keaster, Assistant Professor, Speech and Otology, Speech Clinic, State University of Iowa, Iowa City.

KANSAS

Director of State Board Resigns.—Mr. Paul D. Haney, after fifteen years of service to the Kansas State Board of Health, has resigned the position of director and chief engineer of the division of sanitation, which he has held since 1942, to become an associate professor of sanitary engineering at the University of North Carolina, Chapel Hill. Mr. Ben L. Williamson, Des Moines, has accepted the appointment as director of the division of sanitation.

Establish a Cancer Registry.—The University of Kansas School of Medicine and Hospital, Lawrence-Kansas City, under the direction of the division of cancer control of the state board of health, is establishing a cancer registry. Abstracts of about 800 cases of cancer for the year 1945 from the records of the department of pathology have been completed. Cancer records from the William Newton Memorial Hospital and St. Mary's Hospital at Winfield have also been received. This is one of the initial steps leading to the establishment of diagnostic cancer clinics as approved by the cooperative cancer control group in Kansas, the Kansas Medical Society, the Kansas Division, American Cancer Society, and the Kansas State Board of Health.

LOUISIANA

University Appointments.—The Louisiana State University School of Medicine, New Orleans, announces the following faculty appointments: Dr. Jerome T. Syverton, formerly associate professor of bacteriology, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., as professor and head of the newly formed department of microbiology; Dr. Curtis J. Lund, Madison, Wis., formerly associate professor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, as professor of obstetrics and gynecology on a full time basis; Harold L. Brauer, instructor in pharmacology, Harvard Medical School, Boston, as assistant professor of pharmacology; Leon Churney, Ph.D., instructor in physiology, University of Pennsylvania, Philadelphia, as assistant professor of physiology; Dr. Allan L. Segal, instructor in radiology, Columbia University College of Physicians and Surgeons, New York, as clinical assistant professor of radiology; Dr. James A. Wilson, resident in obstetrics and gynecology, Charity Hospital, New Orleans, as full time instructor in obstetrics and gynecology; Dr. Harry D. L. Kaye, assistant in surgery, Yale University as full time instructor in surgery; Dr. Philip B. Johnson, New Orleans, recently released from military service, as instructor in medicine. Other recent appointments include Dr. Juan E. Morales, New Orleans, as clinical assistant in neuropsychiatry; Dr. Marie L. Surgi, New Orleans, as assistant in pediatrics, and Dr. Robert M. Rose, Buffalo, as clinical assistant in orthopedics.

MAINE

Personal.—Dr. John G. Towne, Waterville, has resigned from the Maine Board of Registration of Medicine after eighteen years' service.——Dr. Roscoe L. Mitchell, Augusta, Maine state health director, has been elected vice president of the U. S. Association of State and Territorial Health Officers.

MASSACHUSETTS

Appoint Public Relations Executive.—The Massachusetts Medical Society has announced that a full time public relations executive will become a part of the organization July 1. Dr. John F. Conlin, Boston, a graduate of Tufts College Medical School, Boston, 1938, has been appointed director of medical information and education. After an internship at St. Elizabeth's Hospital, Boston, and a residency at Captain John Adams Hospital in Chelsea, he entered the army in 1942 and was discharged with the rank of colonel in 1946. He is now attending courses at the Harvard School of Public Health.

MICHIGAN

Personal.—Dr. Arthur G. Baker, Grand Rapids, has been appointed health officer of Allegan County. Dr. Baker, a graduate of the University of Michigan Medical School in 1943, formerly was assistant health officer in Calhoun County.

Short Practical Nursing Course.—St. Joseph Mercy Hospital, Pontiac, April 1 began enrolling women between the ages of 17 and 30 for a twelve month basic training session in nursing to prepare auxiliary personnel for the care of the sick. The course will include six weeks of basic training at St. Joseph Mercy Hospital in Detroit. At the end of a year certificates will be issued recognizing each trainee as a practical nurse.

MISSISSIPPI

Annual Meeting at Biloxi.—The annual meeting of the Louisiana-Mississippi Ophthalmological and Otolaryngological Society will be at Biloxi May 5. Drs. Samuel Fomon, New York City, will address the group on "The Rhinoplastic Operation and the Restoration of Nasal Function"; Peter C. Kronfeld, Chicago, "Newer Trends in the Treatment of Ocular Diseases," and Ralph Bowen, Houston, Texas, "Allergic Problems Seen by the Ophthalmologist and Otolaryngologist." The J. Raymond Hume Memorial Address will be delivered by Dr. Henry L. Williams, Rochester, Minn., on "Ménière's Disease."

MISSOURI

Dr. Moore Appointed Dean.—Dr. Robert A. Moore, who has been professor of pathology at Washington University School of Medicine, St. Louis, since 1939 and has served as acting dean of the school of medicine for the past year, has been appointed dean of the school. Dr. Moore is assistant secretary of the American Board of Pathology, editor of the *Journal of Gerontology* and during the war served as civilian resident consultant to the Army Medical Museum and to the Secretary of War on epidemic diseases and on committees of the National Research Council.

NEW JERSEY

New Diabetes Association.—The New Jersey Diabetes Association, affiliated with the American Diabetes Association, has been organized with Dr. Benjamin I. Saslow, Newark, chairman of the organizing committee. Disseminating knowledge of diabetes, educating the public, cooperating with associated groups and conducting clinical, experimental and demographic studies of diabetes are its aims. Interested physicians should contact Dr. Saslow at 102 Shanley Avenue, Newark 8.

Cooperative Mosquito Control.—Wallace T. Eakins of the state department of health, Trenton, in an address before the annual meeting of the New Jersey Mosquito Extermination Association April 4, reported that since the cooperative plan of malaria control went into effect in New Jersey in 1944 only 12 persons were known to have been infected by malaria within the state; however, 3,000 cases of imported malaria have been reported in New Jersey since 1944, mainly among returned service men.

Diphtheria Increased in 1946.—Reports received by the state department of health show that all but one of the twenty-one counties in the state reported cases of diphtheria in 1946, making a total of 120. The increase in cases over the previous year was 80 per cent. Counties reporting the largest number of cases were Camden, Hudson and Middlesex. The state department of health provides sixty distributing stations throughout the state where toxoid can be obtained by physicians free of charge.

NEW YORK

Four County Clinic Day.—Genesee, Livingston, Orleans and Wyoming County medical societies met April 9 in Rochester for an all day clinic program. Subjects discussed were "Gynecology in General Practice," "Plasma Therapy in Medicine, Surgery and Emergencies," "Tumors of the Gastrointestinal Tract" and "Diagnosis and Management of Rheumatic Fever." Dr. Konrad E. Birkhaug, Albany, New York State Department of Health, delivered the dinner address on "Immunization with BCG."

Personals.—Governor Dewey has appointed Dr. Frank A. Mastrianni of Mechanicsville coroner of Saratoga County to succeed the late Dr. Arthur W. Johnson. Dr. Mastrianni is president of the Saratoga County Medical Society and has been health officer of Mechanicsville for many years.——Dr. Ray E. Persons, Cairo, has been elected president of the Greene County Memorial Hospital staff to succeed Dr. T. Earl McQuade.——Dr. George Weber, Albany, has been appointed full time medical director of the Ulster County Tuberculosis Hospital at Kingston.

New York City

Personal.—At the 100th graduating exercises of Hahnemann Medical College and Hospital of Philadelphia, April 3, Dr. Samuel Weiss, New York, was awarded the degree of Doctor of Science.

Extend Children's Diagnostic Services.—An extension of the diagnostic service of the Children's Tumor Registry of Memorial Hospital was made early this year, with the establishment of the Children's Diagnostic Clinic. The service is offered to pediatric patients of hospitals and private physicians for the diagnosis of neoplastic disease and is available for ambulant or bed cases. The investigations will be performed at cost or without charge if the patient is unable to pay. On completion of the study the patient will be referred to the physician or institution interested, with a report of the findings. If therapeutic recommendations are indicated and requested, they will be made. Appointments may be made by mail or telephone.

OHIO

Annual State Medical Meeting.—The annual meeting of the Ohio State Medical Association will be held in Cleveland May 6-8 in the Public Auditorium and Hotel Cleveland under the presidency of Dr. Edgar P. McNamee, Cleveland. Speakers at the general sessions include:

Dr. Theodore L. Squier, Milwaukee, Hazard of Drug Hypersensitivity in Chemotherapy.
Dr. Philip Levine, Raritan, N. J., Clinical Importance of the Rh Factor.
Dr. John Q. Griffith Jr., Philadelphia, Rutin: Therapy for Capillary Abnormality in Hypertension.
Dr. Alan F. Guttmacher, Baltimore, Artificial Insemination: Indications and Technic.
Dr. Jerry C. Price, New York, Care of the Epileptic Person.
Dr. Zacharias Bercovitz, New York, Diagnosis and Treatment of Diarrheas and Dysenteries.
Dr. Andrew H. Dowdy, Rochester, N. Y., The Age of Atomic Power.

A new feature of the sessions are the instructional courses providing practical lectures and demonstrations on questions and problems arising most frequently in everyday practice. Cards for admission may be obtained in advance of the meeting on application to the Columbus Office, Ohio State Medical Association.

PENNSYLVANIA

Personal.—Dr. Ernest G. Williamson, Philadelphia, for many years resident surgeon at Presbyterian Hospital, has been appointed chief surgeon there. He is a graduate of Jefferson Medical College of Philadelphia and later completed postgraduate work at the University of Edinburgh, Scotland.

Philadelphia

Dr. Lahey to Lecture.—The first annual Phi Delta Epsilon lecture at the Hahnemann Medical College and Hospital of Philadelphia will be delivered by Dr. Frank H. Lahey, director, Lahey Clinic, Boston, May 12 on "Surgery of the Stomach, Duodenum and Jejunum."

RHODE ISLAND

Annual State Medical Meeting.—The Rhode Island Medical Society will hold its 136th annual meeting May 14-15 in the society's library at Providence under the presidency of Dr. Herman C. Pitts, Providence. The Charles V. Chapin Oration will be delivered by Dr. Stanhope Bayne-Jones, professor of bacteriology, Yale University School of Medicine, New Haven, on "Control of Typhus Fever." He will receive the Chapin Medal award from the city of Providence at the dinner meeting at the Narragansett Hotel. Among the speakers for the general program will be:

Dr. Malcolm J. Farrell, Waverly, Mass., Psychiatric Lessons Learned in the Army.
Dr. Chester S. Keefer, Boston, Antibiotic Agents in Clinical Medicine.
Dr. Elmer L. Sevringhaus, Nutley, N. J., Use of Estrogens and Progesterone.
Dr. William D. Wolfe, Baltimore, Common Dermatologic Conditions and Their Treatment.

WEST VIRGINIA

Rapid Treatment Center Transferred to State Department.—The Kanawha Valley Medical Center, the state's rapid treatment center, South Charleston, was transferred April 1 from the federal government to the state department of health. The present staff of forty-five, including two doctors, is being retained. During the three years the center was operated by the government 10,341 persons were treated. Of these, more than one fourth were under 21 years of age, 17.4 per cent between 18 and 21, and 1.3 per cent infants under 1 year of age. Other persons treated have ranged up to more than 60 years of age. The cost per patient for the treatment of syphilis has been about $46. After July 1 the state will probably assume about 30 per cent of the cost of the center.

Annual State Medical Meeting.—The eightieth annual meeting of the West Virginia Medical Association will be held at Charleston, May 12, under the presidency of Dr. Wade H. St. Clair of Bluefield. As usual, there will be no section meetings, but all the sections and affiliated societies will have representation on the program. Only the Tuesday night session will be held in the Daniel Boone Hotel. All other meetings, including both sessions of the house of delegates, will be held in the auditorium at the Shrine Mosque. Among the speakers at the scientific sessions will be:

Dr. Norman Treves, New York, Diagnosis and Treatment of Cancer of the Breast.
Dr. James G. Arnold, Baltimore, Prefrontal Lobotomy.
Dr. Emmerich von Haam, Columbus, Ohio, Clinical and Pathologic Concept of Hypersplenism.
Marjorie Shearon, Ph.D., Washington, D. C., Bureaucratic Control of Medicine.
Dr. James W. Bruce, Louisville, Ky., Infant Diarrhea.
Dr. Mark L. Gerstle Jr., New York, Psychiatry and the General Practitioner.
Dr. Joseph T. Beardwood, Philadelphia, The Modern Use of Insulin.
Dr. Walter C. Alvarez, Rochester, Minn., Puzzling Types of Abdominal Pain.
Dr. Arthur M. Master, New York, Diagnosis and Treatment of Acute Coronary Diseases.
Dr. Harrison H. Shoulders, Nashville, President, American Medical Association, Some Problems in the Economics of Medical Care.
Dr. R. Townley Paton, New York, Corneal Grafts.
Dr. John H. Foulger, Wilmington, Del., New Method of Studying Efficiency of the Heart and Circulation.
Dr. Louis H. Douglas, Baltimore, Abdominal Pregnancy.
Dr. Robert L. Bennett Jr., Warm Springs, Ga., Responsibility of the Physician in the Care of Acute and Convalescent Poliomyelitis.

Entertainment includes section and society luncheons, the past president's dinner Sunday night, a dance Tuesday night, a tea and reception at the executive mansion Wednesday afternoon, the annual banquet and ball Wednesday evening and the annual tennis and golf tournaments.

WISCONSIN

Appoint Professor of Physical Medicine.—Dr. Harry D. Bouman, formerly assistant professor of physical medicine, Northwestern University Medical School, Chicago, has been appointed associate professor of physical medicine at the University of Wisconsin Medical School, Madison. Dr. Bouman, a graduate of the University of Amsterdam, has held a Skostokvis Research Fellowship at the University of Paris and was a Rockefeller Foundation fellow in neurophysiology at University College, London. During the past six years his research has been directed toward the problem of infantile paralysis.

Psychologic and Psychiatric Aspects of Pediatric Practice.—An opportunity for study of the emotional, psychologic and psychiatric problems in pediatric practice is to be made available to those who are directing their work into these areas through the facilities of the University of Wisconsin Medical School, Madison, and the Wisconsin State Board of Health. This work will be given at the medical school and the State of Wisconsin General Hospital, Madison, from April 28 to May 18. Dr. Benjamin M. Spock, now associated with the Mayo Clinic, Rochester, Minn., as psychiatric consultant in pediatrics, and Dr. Milton J. E. Senn, associate professor of pediatric psychiatry, Cornell University Medical College, New York, will direct the work. Further details will be available through Dr. Llewellyn R. Cole, Coordinator of Graduate Medical Education, the Medical School, 418 North Randall Avenue, Madison 6, Wis.

HAWAII

Annual Medical Meeting.—The annual meeting of the Hawaii Territorial Medical Association will be held May 1-4 at the Lihue Parish House, Lihue, Kauai, under the presidency of Dr. Jay M. Kuhns, Lihue. Dr. Cyrus C. Sturgis of Ann Arbor, Mich., will speak on "Thirty Years' Experience with Coronary Artery Disease." Among other presentations will be:

Dr. Rogers L. Hill, Honolulu, Acute Appendicitis in Measles.
Dr. Tell Nelson, Honolulu, Management of the Allergic Patient.
Dr. Edward F. Slaten, Honolulu, Familial Erythroblastic Anemia.
Dr. Joseph E. Strode, Honolulu, Tumors Within or Adjacent to the Mediastinum.

GENERAL

Special Society Elections.—At a meeting of the Tri-State Medical Association in Greensboro, N. C., Dr. Charles N. Wyatt, Greenville, S. C., was made president-elect and Dr. S. Raymond Thompson, Charlotte, became president of the association.

Rockefeller Foundation Appropriations.—The Rockefeller Foundation, which made appropriations totaling $19,481,576 during 1946, gave $1,395,985 to aid in medical science. Of this amount $360,435 was made to psychiatry, neurology and allied sciences, $272,000 to endocrinology, $75,350 to medical education, $88,200 to group medicine and medical economics and $600,000 to fellowships and grants-in-aid.

Allergy Research Fund.—The American College of Allergists announces a grant of $1,500 from Luziers, Inc., Kansas City, Mo., for continuation of allergy research in the field of dermatology. This fund will be under the direction of Dr. Rudolph L. Baer, assistant attending physician, New York Skin and Cancer Hospital, New York, and Dr. Stephan Epstein, Marshfield Clinic, Marshfield, Wis.

The S. S. Frederick Banting.—At the request of a group of American physicians in 1943 the U. S. Maritime Commission named a liberty ship in honor of Sir Frederick Banting, the discoverer of insulin. In doing so the rule that all American ships must be named for citizens of this country was set aside. The ship was presented to the British commonwealth. Since Dec. 30, 1943, when the ship was delivered under lend lease, it has been operated by the British to ports in Japan, China, Australia, India, the Mediterranean and Canada.

Venereal Disease Pamphlets.—The U. S. Public Health Service has just issued three new publications to spur an effective educational program concerning venereal disease: "Facts About Syphilis and Gonorrhea," "Wedding Plans" and "Protecting the Unborn Baby." Sample copies are available free on request to U. S. Public Health Service, Washington 25, D. C., or quantity orders may be purchased from the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

Traffic Safety Awards.—Connecticut and Washington, D. C., have been named grand award winners in the 1946 National Traffic Safety Contest conducted by the National Safety Council. From the 1,355 cities participating in the contest, the annual special awards for sustained records in excellence in traffic safety for five or more consecutive years were given to Milwaukee and Beaver Dam, Wis.; Stillwater, Okla., and Coshocton, Ohio. Cities competing in the contest represented more than 90 per cent of the present population of the United States.

Clinical Research on New Drug.—Dr. William A. Nicholson, Duke Hospital, Durham, N. C., and Dr. Robert A. Goodwin, Vanderbilt University Hospital, Nashville, Tenn., have been awarded research grants by Sharp and Dohme, Inc., Philadelphia, it was announced February 19. Both grants are in support of clinical studies on the evaluation of caronamide, 4'carboxyphenylmethanesulfonamide, a new drug. Used in conjunction with penicillin, caronamide is said to inhibit the excretion of penicillin from the body and serves to maintain high therapeutic concentrations of the antibiotic in the blood for longer periods of time.

Birth Rate Increasing in United States.—According to the March issue of the United Nations Monthly Bulletin of Statistics, the United States birth rate is the highest in history. Decreasing steadily from 1915 to a low point in 1933, the rate in the United States rose from 17.1 births per thousand inhabitants in 1937 to an annual rate of 28.8 in November 1946. Of the twenty countries included in the tables, Uruguay, Chile and Belgium are static and India and Egypt show noticeable declines. Palestine showed the highest birth rate, 43.4. The trend of the birth rate in World War II differs from that in World War I. A drop occurred during World War I and a slight rise only after the Armistice, while in this decade a general rise has occurred through the war years.

Special Society Elections.—At a recent meeting the American College of Allergists elected Drs. Hal M. Davison, Atlanta, Ga., president-elect; George E. Rockwell, Milford, Ohio, and Willard S. Small Jr., Pasadena, Calif, vice presidents, and Frederick W. Wittich, Minneapolis, secretary-treasurer. Dr. Leon Unger, Chicago, was installed as president.——The Society of Physical Medicine has elected Drs. Earl C. Elkins, Rochester, Minn., president; Miland E. Knapp, Minneapolis, vice president; Milton G. Schmitt, Chicago, secretary-treasurer. Dr. William D. Paul, Iowa City, was installed as president.——The American Board of Pathology announces the election of Drs. Nathan C. Foot, New York, president; William Sunderman, Philadelphia, vice president, and Robert A. Moore, St. Louis, secretary-treasurer.——The Central New York Eye, Ear, Nose and Throat Society has elected Drs. Uri Doolittle president and Alfred W. Doust, both of Syracuse, secretary.

Records of Committee on Medical Research, OSRD.—In closing the office of the Committee on Medical Research of the Office of Scientific Research and Development, Washington, D. C., the records that accumulated during the war years 1941-1946 are being distributed to libraries throughout the country in order that they may be available to interested persons. Among the records so distributed are complete sets of the seventy-eight issues of the (1) weekly bulletin entitled "Summary of Reports Received by the Committee on Medical Research"; these bulletins contain abstracts of the "open" and "restricted" reports received from investigators; (2) bound and indexed sets of reprints of published work done under OSRD-CMR contracts; (3) indexed sets of the 734 numbered reports issued by the Board for the Coordination of Malarial Studies; (4) Aviation Medicine Reports: a complete set of the 505 numbered reports issued by the National Research Committee on Aviation Medicine; (5) final and interim reports of CMR investigators. Copies of almost all these reports are on file in the Office of Medical Records, National Research Council, 2101 Constitution Avenue, Washington, D. C., where they can be consulted but cannot be sent out on loan.

Danger in the Kitchen.—The Statistical Bulletin of the Metropolitan Life Insurance Company estimates from studies among Metropolitan industrial policyholders and among other groups that about 6,000 persons are killed annually in the United States from mishaps in the kitchen and that many times that number are injured more or less seriously, though not fatally. In no other room in the house does such a concentration of hazards exist. The most frequent type of fatal accident in the kitchen is burns and scalds. Falls, which rank second, are said to be responsible for about 1,500 deaths in kitchens annually. Among the hazards contributing to these falls are wet or waxed floors, worn linoleum or other floor coverings, unanchored small rugs, pails or other objects left on the floor; falls from tables, ladders, windows, chairs and highchairs. Gas poisoning is a relatively frequent cause of accidents in the kitchen, more particularly among men who doze off while heating coffee or other fluids which boil over and put out the gas flame. Trouble may arise from a defective pilot light which is out or is not functioning; gas jets may be turned on unknowingly by persons brushing against them; some people may turn on the gas and forget to light it. Other contributing conditions to such deaths are burning gas with an excessively high flame in a poorly ventilated kitchen, improperly installed heaters and gas appliances in poor repair. Fatalities in the kitchen are also caused not infrequently by such poison compounds as roach powders or rat poisoning carelessly kept and mistakenly used for flour or baking powder. The modern kitchen is a combination bakery, cannery, laundry, restaurant, factory and butcher shop and playground. In industry, where similar hazards exist, either state officials or trained employees help to control accidents, but in the home this responsibility usually falls on the woman of the house, who should know where the chief dangers lie.

CANADA

Personal.—Dr. Kenneth E. Dowd, Montreal, Que., chief medical officer of the Canadian National Railways and Trans-Canada Air Lines since 1943, has been elected chairman of the medical and surgical section of the Association of American Railroads. During the second world war he served as medical consultant in civil aviation to the Royal Canadian Air Forces and as chief medical consultant of the Royal Air Force Ferry Command.

LATIN AMERICA

Personal.—Dr. Guillermo Diaz, Lima, Peru, who recently visited the headquarters of the American Medical Association in Chicago, is head of the National Department of Sanitary Education in Peru. With a scholarship from the Institute of Inter-American Affairs he will do postgraduate work on public health and sanitation and visit American medical centers.

New Medical Journal.—*Archivos de Neuro-Psiquiatria,* the official organ of the Sanatorio Dr. Galigarcia, which recently appeared, is a quarterly journal with editorial headquarters in Havana, Cuba. The second issue, September 1946, contains sections of editorials, medical news, original articles and abstracts of articles. Some of the articles are translated from English or Portuguese medical journals.

FOREIGN

Great Britain

Plans for National Health Services.—The National Health Service Act will probably come into operation on April 1, 1948. Mr. Aneurin Bevan, minister of health, recently made this announcement to the local health authorities, according to British Information Services, when he asked them to start reorganizing the home and health services for which they will be responsible under the act—services which will provide free health care to all residents of Britain regardless of their financial status. Mr. Bevan gave the following time table for submitting proposals concerning the reorganization of the various services:

Vaccination and immunization	June 30, 1947
Ambulance services	
Midwifery	August 31, 1947
Health nursing	
Prevention of illness, care and after care	
Domestic help	
Duties under lunacy and Mental treatment act and Mental deficiency acts	
Care of mother and young children	September 30, 1947
Health centers	November 30, 1947

The aim is to frame plans which will provide as efficient and comprehensive a service as prevailing conditions permit. The membership of the health committee of each local health authority must be considered. The act provides that while a majority of the health committee must be members of the parent authority, outside persons may also be appointed, thus allowing the inclusion of doctors and other experts. Mr. Bevan has also suggested that, in view of the nature of the services with which the committee will be concerned, its membership should include an adequate proportion of women. Preliminary proposals about the provision of health centers will cover the reservation of suitable sites for such centers.

Marriages

Paul A. Meredith, Caro, Mich., to Miss L. Virginia Hunter of Howard, Kan., in Chicago Nov. 22, 1946.

Norman Balfour Kanof, Richmond, Va., to Miss Joan Winifred Sher of Brooklyn Dec. 15, 1946.

Charles Hyatt Place, Poundridge, N. Y., to Miss Ruth Evelyn Murray of Brooklyn January 18.

Wilfred S. Miller, Assumption, Ill., to Mrs. Felice Connolly of Taylorville in Kewanee Nov. 25, 1946.

David Marcus, Astoria, N. Y., to Miss Shirley Lenore Edelstein of Rego Park recently.

Max Benjamin Milberg, Brooklyn, to Miss Lillian Gertrude Kling of New York March 9.

William I. Poole, Calvert City, Ky., to Mrs. Verda Lawson of Paducah Dec. 10, 1946.

Samuel Myerson to Miss Phyllis Greenhill, both of New York, March 16.

Deaths

Martin Aaron Bernfield ⊕ San Antonio, Texas; born in Jaffa, Palestine, July 19, 1892; University of Michigan Medical School, Ann Arbor, 1929; interned at the City of Detroit Receiving Hospital; during World War I served as an intelligence officer in the Russian army; later joined the British army and served in the Upper Sudan campaign in 1919; at the outbreak of World War II was commissioned passed assistant surgeon in the U. S. Public Health Service with the rank of captain; at the time of his death was associated with the San Antonio regional office of the Veterans Administration as medical officer full grade, neuropsychiatric examiner; died Aug. 22, 1946, aged 54, of coronary thrombosis and embolus of the abdominal aorta.

Ira Price Burdine Jr. ⊕ Amory, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1931; interned at the Charity Hospital in New Orleans and the Mississippi State Charity Hospital in Jackson; served a residency at the Mississippi State Tuberculosis Sanatorium in Sanatorium; began active duty as a captain in the medical corps, Army of the United States, on Sept. 29, 1942; promoted to major; released from service Aug. 27, 1946; died in the (Kennedy) Veterans Administration Hospital, Memphis, Tenn., Oct. 29, 1946, aged 40, of acute gastritis and congestion of the lungs.

James Darrah Osborn ⊕ Frederick, Okla.; born Dec. 23, 1879; Medical Department of Tulane University of Louisiana, New Orleans, 1901; served as secretary of the Oklahoma State Board of Medical Examiners and Board of Examiners in the Basic Sciences; president of the Oklahoma State Medical Association; member of the National Board of Medical Examiners; president-elect of the Federation of State Medical Boards; formerly superintendent of public health; killed February 7, aged 67, when a St. Louis bound Frisco passenger train was derailed at Republic, Mo.

Isaac Rosenbaum Pels ⊕ Baltimore; born in Baltimore, Oct. 8, 1881; Johns Hopkins University School of Medicine, Baltimore, 1906; assistant professor of dermatology at his alma mater; specialist certified by the American Board of Dermatology and Syphilology; member of the American Dermatological Association and the American Academy of Dermatology and Syphilology; on the staffs of the Johns Hopkins, Bon Secours, Sinai, Union Memorial and Baltimore City hospitals and the Church Home and Infirmary; died February 4, aged 65, of cardiovascular disease.

James Cox Archer ⊕ Senior Surgeon, U. S. Public Health Service, Fort Stanton, N. M.; Baylor University College of Medicine, Dallas, 1933; entered the U. S. Public Health Service in 1934; in charge of the U. S. Marine Hospital, where he died February 1, aged 43, of coronary occlusion.

Peter C. Berns, Linton, Ind.; Missouri Medical College, St. Louis, 1897; member of the American Medical Association; served with the British army during World War I; died January 16, aged 74.

Marshall Merrill Best, Honolulu, Hawaii; University of Cincinnati College of Medicine, 1927; member of the American Medical Association and the Ohio State Medical Association; awarded the Bronze Star medal for meritorious service during World War II; died January 3, aged 46.

Zelly Adam Bonoff, New Haven, Conn.; Yale University School of Medicine, New Haven, 1904; died in the New Haven Hospital January 30, aged 66, of arteriosclerotic heart disease.

Andrew Jackson Brown, Clarksdale, Miss.; Chicago College of Medicine and Surgery, 1909; member of the American Medical Association; at one time member of the state board of medical examiners; formerly superintendent of the State Charity Hospital in Natchez; died January 30, aged 71, of carcinoma of the liver.

John Thomas Brown, Forrest City, Ark.; Memphis (Tenn.) Hospital Medical College, 1885; died in a hospital at Memphis, Tenn., January 22, aged 84, of a hip fracture received in a fall.

Joseph R. Burdett, Tennille, Ga.; Bellevue Hospital Medical College, New York, 1889; member of the American Medical Association; died Dec. 9, 1946, aged 84.

Lilburn Ira Burrows, Batesburg, S. C.; Baylor University College of Medicine, Dallas, Texas, 1932; interned at St. Anthony Hospital in Oklahoma City; formerly a medical missionary in India; served during World War II; died in the Veterans Administration Hospital, Columbia, February 27, aged 45, of cirrhosis of the liver.

George Hull Camp, Springfield, Mo.; Emory University School of Medicine, Atlanta, 1920; member of the American Medical Association; served during World War I and II; affiliated with St. John's Hospital, where he died January 29, aged 53, of uremia.

Bernard McHugh Cline ⊕ Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1905; affiliated with St. Joseph Infirmary, Georgia Baptist Hospital and the Crawford W. Long Memorial Hospital; died January 26, aged 65, of coronary thrombosis.

Allan Loeb Cohn, Shreveport, La.; University of Wisconsin Medical School, Madison, 1937; member of the American Medical Association; for many years a member of the Caddo-Shreveport health unit; died January 22, aged 35.

William Corns, Tama, Iowa; Drake University Medical Department, Des Moines, 1900; member of the American Medical Association; served during World War I; formerly on the staff of the Iowa Soldiers' Home at Marshalltown; died January 26, aged 73, of carcinoma of the stomach.

Anna Elizabeth Mulheron Coyle, Windsor Locks, Conn.; Woman's Medical College of Pennsylvania, Philadelphia, 1912; member of the American Medical Association; school physician and assistant health officer; died January 27, aged 62, of coronary thrombosis.

William Hartwell Cressy, Brooklyn; Chicago College of Medicine and Surgery, 1909; Medical Department of Tulane University of Louisiana, New Orleans, 1914; medical officer in the Serbian army during World War I; died in the Methodist Hospital January 12, aged 67.

Alden Larue Crittenden ⊕ Wichita, Kan.; Rush Medical College, Chicago, 1912; fellow of the American College of Surgeons; on the staff of the Wesley Hospital; died January 20, aged 63, of leukemia.

William Donovan, New York; Bellevue Hospital Medical College, New York, 1898; member of the American Medical Association; died in the Lenox Hill Hospital January 30, aged 78.

Alice Barker-Ellsworth, Long Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; member of the American Medical Association; a medical officer in the army during World War I; served on the Los Angeles County Child Welfare Board; past president of the Women's Medical Association of Los Angeles County; died January 7, aged 70, of cerebral hemorrhage.

Fred Leslie Ervay, Fredonia, Kan.; Keokuk Medical College, College of Physicians and Surgeons, 1908; also a dentist; for many years member of the board of education; died January 22, aged 66, of carcinoma of the bladder.

John O'Fallon Farrar, St. Louis; Barnes Medical College, St. Louis, 1896; died January 25, aged 79, of carcinoma of the liver.

Frank Crist Fisher, Bloomington, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the American Medical Association; on the staff of the Brokaw Hospital and member of the board of the Fairveiw Sanatorium, Normal; an examiner on the U. S. Exemption Board of Bloomington during World War I; died January 24, aged 78, of coronary thrombosis.

Cornelius A. Fossum, Joplin, Mo.; Loyola University School of Medicine, Chicago, 1919; died Dec. 17, 1946, aged 56.

Johanna Gelien, Berkeley, Calif.; Denver and Gross College of Medicine, 1908; member of the American Medical Association and the Colorado State Medical Society; died January 28, aged 78, of coronary occlusion.

John Relda Gideon, Joiner, Ark.; Mississippi Medical College, Meridian, 1912; Kansas City (Mo.) College of Medicine and Surgery, 1920; died January 9, aged 61.

Stowell Burrough Grant, Munnsville, N. Y.; Albany (N. Y.) Medical College, 1906; member of the American Medical Association; past president of Madison County Medical Society; school physician; on the staff of the Oneida City (N. Y.) Hospital; died in Oneida January 23, aged 65, of coronary thrombosis.

Charles William Hamilton, Hood River, Ore.; University of Oregon Medical School, Portland, 1914; city health officer; on the staff of the Hood River Hospital; died in Coos Bay recently, aged 60, of carcinoma of the head of the pancreas.

Charles Merrill Hazard ⊕ Arlington, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1910; served during World War I; died January 30, aged 61, of cerebral hemorrhage.

James Henry Hill, Talladega, Ala.; Birmingham Medical College, 1909; member of the American Medical Association; served as secretary of the Talladega County Medical Society; county health officer; died January 19, aged 66, of right ventricular failure and renal disease.

Charles Edwin Hood, Ann Arbor, Mich.; Detroit College of Medicine, 1898; at one time health officer of Drayton, N. D.; died in the University Hospital January 29, aged 80, of bronchopneumonia.

John Jones Jack, Stamps, Ark. (licensed in Arkansas in 1903); served as health officer; died January 12, aged 76.

Harry Jarmulowsky ⊕ Paterson, N. J.; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Prussia, Germany, 1906; on the staffs of the Barnert, General and St. Joseph's hospitals; died January 27, aged 69, of hypertensive heart disease.

J. H. Johns, Westminster, S. C.; Atlanta Medical College, 1898; formerly state senator; died January 28, aged 72.

Grace Elizabeth Atkins Jordan, Boston; Boston University School of Medicine, 1899; died January 15, aged 74, of carcinoma of the kidney.

John McLean Karch, Cincinnati; Ohio State University College of Medicine, Columbus, 1929; member of the American Medical Association; began active duty as a captain in the medical corps, Army of the United States, Sept. 2, 1942; released from service Jan. 19, 1945; served an internship at the Good Samaritan Hospital, where he was on the staff; accidentally killed while hunting February 12, aged 47.

Thomas Junior Kemp, Clayton, Mo.; Columbian University Medical Department, Washington, D. C., 1900; past president of St. Louis County Medical Society; member of the American Medical Association; on the staffs of the Faith and Park Lane Memorial hospitals; died January 23, aged 72, of heart disease.

Frank Peter Knabb ⊕ Valley Park, Mo.; Barnes Medical College, St. Louis, 1902; past president of St. Louis County Medical Society; president of the school board; died in the Missouri Baptist Hospital, St. Louis, January 29, aged 71, of uremia.

William Roscoe Koob, Brayton, Iowa; Ensworth Medical College, St. Joseph, 1892; member of the American Medical Association; died in Long Beach January 16, aged 77, of coronary occlusion.

Lorenz Kronrad, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1935; member of the American Medical Association; served during World War II; died January 19, aged 35, of coronary occlusion.

Jean Baptiste LaBorde, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1918; member of the American Medical Association; served during World War I, as chairman of the city board of health and as county physician; died January 3, aged 53.

Bernard Vincent Lally, Tiffin, Ohio; Eclectic Medical College, Cincinnati, 1937; member of the American Medical Association; served on the staffs of St. Mary's and Deaconess hospitals in Evansville, Ind.; director of health for Seneca County; died January 28, aged 40, of heart disease, following pneumonia.

Asher Noah Lebensohn, Washington, D. C.; Northwestern University Medical School, Chicago, 1938; interned at Los Angeles County Hospital; formerly on the staffs of the Veterans Administration facilities in San Fernando, Calif., and Wadsworth, Kan.; served during World War II; died Dec. 17, 1946, aged 33.

Clarence Wyman Lincoln, Wayne, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; served during World War I; died in the Bryn Mawr (Pa.) Hospital January 22, aged 80, of uremia.

John Linder, Neponsit, N. Y.; University and Bellevue Hospital Medical College, New York, 1904; fellow of the American College of Surgeons; served as clinical professor of surgery at the Long Island College Hospital in Brooklyn, where in 1937 a plaque was presented to the Jewish Hospital in recognition of his service as a member of the medical staff; served on the staff of the Beth-El Hospital; died January 12, aged 64.

William H. Little, Alta Vista, Kan.; Kansas City (Mo.) Medical College, 1900; died in Phoenix, Ariz., January 21, aged 78, of cerebral hemorrhage and arteriosclerosis.

George Emory Lochner, Albany, N. Y.; Albany Medical College, 1889; member of the American Medical Association; formerly clinical professor of gynecology at his alma mater; chief of staff at the Brady Maternity Home since its establishment; on the staff of the Memorial Hospital; died January 29, aged 79, of jaundice and intestinal obstruction.

Thomas Dick Longino, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1870; Jefferson Medical College of Philadelphia, 1882; member of the American Medical Association; Civil War veteran; served on the city council, at various times mayor of Palmetto, mayor of West End when it was a separate corporation from Atlanta and as mayor pro tem of Atlanta; on the board of trustees of the Grady Hospital; died in St. Joseph's Infirmary January 28, aged 100, following prostatic resection.

John Roy McKnight ⊕ Colonel, U. S. Army, retired, Bellwood, Pa.; Jefferson Medical College, Philadelphia, 1906; Army Medical School in 1911; entered the medical corps of the U. S. Army as a first lieutenant in March 1911; served during World wars I and II; rose through the various ranks; became colonel on March 19, 1937; retired April 5, 1945; died January 22, aged 66, of heart disease.

Burton Maltby ⊕ Liberty, Mo.; University Medical College of Kansas City, 1908; served with the British army during World War I and was awarded the British Military Cross; served as county physician, county coroner, member and president of the school board; on the visiting staffs of the Research Hospital in Kansas City and the Excelsior Springs (Mo.) Hospital, where he died January 29, aged 61, of cerebral hemorrhage and carcinoma of the colon.

Charles Raysor May, Bennettsville, S. C.; Medical College of the State of South Carolina, Charleston, 1897; member of the American Medical Association; honorary member, past president and formerly councilor of the Sixth District of the South Carolina Medical Association; past vice president of the Tri-State Medical Association; on the staff of the Marlboro County General Hospital; died January 21, aged 74, of coronary thrombosis.

William Charles Meacham, Oak Park, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; served overseas during World War I and received the Croix de Guerre and several other citations; physician for the Chicago Black Hawks hockey team and the Chicago Cardinals football team; died February 11, aged 60, of coronary occlusion.

Edward Frederick Meyer, Chicago; Jenner Medical College, Chicago, 1900; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; served on the staff of the Augustana Hospital; died in St. Mary of Nazareth Hospital January 26, aged 81, of arteriosclerosis.

Stafford T. Mitchell, Chicago; Hering Medical College, Chicago, 1895; died February 13, aged 82, of arteriosclerotic myocarditis.

John Claude Moore ⊕ Seattle; Cooper Medical College, San Francisco, 1895; past president of the King County Medical Society; served on the staffs of the old Seattle City and King County hospitals, as trustee of the Doctors Hospital and one of the six doctors who reorganized Maynard Hospital; died February 16, aged 74, of heart disease.

Michael C. Mullen, Chicago; College of Physicians and Surgeons of Chicago, 1894; associate clinical professor of obstetrics and gynecology at the Loyola University School of Medicine; on the staff of the Mercy Hospital; died February 28, aged 76, of coronary thrombosis.

Charles M. Myers, Dowagiac, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1895; served two terms as state representative; city health officer; for many years member of the board of education, serving as president; served on the library board; died in the Lee Memorial Hospital January 24, aged 82, of coronary occlusion.

Henry Hasswell Nadig, Errol, N. H.; Chicago Homeopathic Medical College, 1898; died in Rowayton, Conn., January 31, aged 70, of coronary thrombosis.

Theodore McGeachy Northrop ⊕ Greenville, S. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1934; interned at the Greenville City Hospital; on the staffs of St. Francis and Greenville General hospitals; died January 11, aged 38, of uremia.

Frederick William Nueske, Bayshore, N. Y.; Long Island College of Medicine, Brooklyn, 1932; interned at the Nassau Hospital in Mineola; served during World War II; medical consultant for the department of public welfare of Suffolk County; associate staff member at South Side Hospital; died January 29, aged 39, of coronary occlusion.

Robert P. Oppenhimer, Knoxville, Tenn.; Medical College of Virginia, Richmond, 1891; member of the American Medical Association; served as a member of the city school board; died January 26, aged 78, of lobar pneumonia and arteriosclerosis.

Giovanni Paccione, New York; Regia Università degli Studi di Bologna. Facoltà di Medicina e Chirurgia, Italy, 1912; member of the American Medical Association; served during World War I; on the staff of the New York Eye and Ear Hospital; for many years on the staff of the Columbus Hospital; member of the welfare and health departments; died January 22, aged 60, of coronary thrombosis.

George Baldwin Palmer, Rolfe, Iowa; Chicago Homeopathic Medical College, 1899; died in St. Joseph Mercy Hospital, Fort Dodge, January 6, aged 75, of carcinoma of the pancreas.

Thomas Benjamin Pearman ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1921; member of the Richmond Academy of Medicine and the Southern Medical Association; affiliated with the Retreat for the Sick, Johnston-Willis Hospital, Sheltering Arms Hospital, Medical College of Virginia Hospital and the Grace Hospital, where he died January 12, aged 49, of fibrillation of the heart and hepatic cirrhosis.

Ladislaus Joseph Perenyi, New York; University and Bellevue Hospital Medical College, New York, 1923; member of the American Medical Association; consultant on the staffs of the Mercy and South Nassau Communities hospitals in Rockville Centre; died in Rockville Centre, N. Y., January 19, aged 47, of diabetes mellitus and coronary thrombosis.

Charles Stephen Phalen ⊕ Sparta, Wis.; Northwestern University Medical School, Chicago, 1913; served during World War I; vice president of the staff of St. Mary's Hospital, where he died January 30, aged 64, of coronary occlusion.

Wilson Frank Phillips ⊕ Boston; Boston University School of Medicine, 1898; formerly assistant professor of theory and practice of medicine at his alma mater; consultant in medicine at the Massachusetts Memorial Hospitals, where he died January 29, aged 74, of coronary thrombosis and bronchopneumonia.

Roland Henry Prien ⊕ Gilroy, Calif.; University of Colorado School of Medicine, Denver, 1919; an Affiliate Fellow of the American Medical Assaociation; died January 23, aged 66, of coronary occlusion

James D. Reid, ⊕ Wellsville, Kan.; University Medical College of Kansas City, Mo., 1912; died January 27, aged 65, of carcinoma of the lung.

John Inzer Reid, Montevallo, Ala.; University of Nashville (Tenn.) Medical Department, 1906; member of the American Medical Association; for many years mayor of Montevallo; died in a hospital at Birmingham January 10, aged 65.

John Henry Reynolds, Live Oak, Fla.; University of the South Medical Department, Sewanee, Tenn., 1899; died January 2, aged 73, of arteriosclerosis.

William Weston Reynolds ⊕ Meridian, Miss.; Louisville (Ky.) Medical College, 1898; past president of the Lauderdale County Medical Society; formerly county health officer and member of the state board of health; served as superintendent of the Matty Hersee Hospital; on the staff of the East Mississippi State Hospital; for many years surgeon for the Southern Railway; died in Rush's Infirmary February 2, aged 76.

Joseph Bennett Riddle, Morganton, N. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; member of the American Medical Association; surgeon, North Carolina State Hospital, Morganton; for many years affiliated with the Grace Hospital, where he died January 1, aged 76.

John Franklin Ritter, Maquoketa, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; member of the American Medical Association; died January 29, aged 77, of coronary occlusion.

Clement J. Rider, Bushnell, Ill.; Baltimore Medical College, 1893; died in Des Moines January 28, aged 79, of chronic myocarditis.

Stacy Herman Rinehardt, Harrisburg, Pa.; Jefferson Medical College of Philadelphia, 1909; served during World War I; died February 8, aged 62, of coronary thrombosis

Sherman T. Rogers, New Albany, Ind.; Eclectic Medical Institute, Cincinnati, 1887; member of the American Medical Association; served as health officer; died in the "Silvercrest" Southern Indiana Tuberculosis Hospital February 6, aged 81.

Hugh Beverly Roney, Pittsfield, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1909; member of the American Medical Association; on the staffs of the House of Mercy and Hillcrest hospitals; died January 8, aged 60, of heart disease.

Morris Rosenbaum, New York; Columbia University College of Physicians and Surgeons, New York, 1903; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staffs of the New York Eye and Ear Infirmary and the Mount Sinai Hospital; died February 1, aged 66, of heart disease.

Gerry Weedon Ross, Onsted, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880; president of the Onsted State Bank; died February 5, aged 87, of heart disease.

Oswald Herman Roth, Newark, N. J.; Bellevue Hospital Medical College, New York, 1892; member of the American Medical Association; at one time examining physician at the Essex County Jail and the House of Detention; died February 19, aged 76, of coronary thrombosis.

Charles Dudley Saul, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1901; member of the American Medical Association; formerly clinical professor of medicine at his alma mater; served during World War I; affiliated with St. Luke's and Children's Medical Center; died January 8, aged 66, of heart disease.

Philip Harrison Scherer, St. Louis; St. Louis University School of Medicine, 1914; member of the American Medical Association; fellow of the American College of Surgeons; instructor in surgery at the St. Louis University School of Medicine; assistant surgeon, St. Mary's Group of Hospitals; an officer during World War I; died in the Alexian Brothers Hospital February 6, aged 57, of hemorrhage due to peptic ulcer.

Hugh Murdoch Shannon, El Paso, Texas; Hahnemann Medical College and Hospital of Philadelphia, 1907; member of the American Medical Association; died in the William Beaumont General Hospital, January 27, aged 61, of cerebral hemorrhage and hypertension.

Bennett Marion Shelton ⊕ Brownwood, Texas; Baylor University College of Medicine, Dallas, 1918; fellow of the American College of Surgeons; past president of the Brown County Medical Society; served during World War I; served as director of Brown County Water Improvement District and member and president of the school board; president of the Medical Arts Hospital; died January 30, aged 55, of coronary occlusion.

Mathias Joseph Seifert ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; at one time on the faculty of his alma mater; fellow of the American College of Surgeons; author of several books; on the staffs of St. Mary's of Nazareth Hospital and the Columbus Hospital, where he died January 31, aged 80, of bronchopneumonia and hypernephroma.

Roswell Haydn Smith ⊕ Edgartown, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1922; chairman of the school board; on the staff of the Martha's Vineyard Hospital, Oak Bluffs; died February 12, aged 52, of cerebral hemorrhage.

Edward Henry Spiegelberg ⊕ Boscobel, Wis.; Rush Medical College, Chicago, 1906; councilor of the Fourth District of the State Medical Society of Wisconsin; died in Milwaukee January 26, aged 65, of coronary occlusion.

Albert Edward Stickley ⊕ Coopersville, Mich.; Grand Rapids Medical College, 1907; veteran of the Spanish-American War and World War I; for many years a member and past president of the board of education; died in the Hackley Hospital, Muskegon, January 23, aged 73, of ruptured aortic aneurysm.

Lydia Webster Stokes, Woodbury, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1894; died January 19, aged 76, of carcinoma of the breast.

Clarence Manley Thomas ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1907; served during World War I; chief anesthetist, South Side Hospital; died January 19, aged 64, of coronary thrombosis.

Robert Lester Waite ⊕ Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1909; on the staff of the Hartford Hospital, where he died January 6, aged 64, of arteriosclerotic heart disease.

Allen Augustus Weeden ⊕ Woonsocket, R. I.; Tufts College Medical School, Boston, 1905; served during World War I; a medical officer for the North Smithfield draft board during World War II; for many years affiliated with Woonsocket Hospital, where he died January 27, aged 75.

Herbert Q. White, Grand View, Ind.; University of Louisville (Ky.) Medical Department, 1893; served as county coroner; died February 7, aged 76, of heart disease.

Gillespie Blaine Yeaney ⊕ Clearfield, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; chief of medical staff of the Clearfield Hospital; died January 31, aged 67, of coronary occlusion.

Appalling Corruption in the Nursing Service of the Egyptian State Hospitals

Dr. A. Cecil Alport, a British physician who was professor of clinical medicine and director of the medical unit, King Fuad First Hospital, University of Cairo, Egypt, has in a book entitled "One Hour of Justice, the Black Book of the Egyptian Hospitals," revealed an almost incredible state of corruption in the nursing service which is performed by males, known as tamargis. Briefly, if the patients, who are poor peasants, have not enough money to bribe the nurses they suffer not only neglect but ill treatment. They are robbed and even assaulted. Some develop what the Egyptian professors term "endogenous hospital disease," disease contracted in a hospital, such as dysentery and enteric fever from flies and pneumonia from unheated wards. The poor who can help it never go into the state hospitals. Europeans and Egyptians never send their servants to these hospitals if they can get them, by payment, into the Christian Mission Hospital or other nongovernment hospitals. In the government hospitals the male nurses are blackmailing gangsters of the worst type. They make patients pay for the medicine ordered for them and the food to which they are entitled. Apart from their blackmailing activities the tamargis steal hospital equipment, instruments, medicine and food.

When Professor Alport could no longer endure these and other scandals in hospital administration he sent his resignation to the university authorities. They sent the professor of anatomy to try to induce him to withdraw his resignation, but he refused. The emeritus professor of physiology followed on the same errand, with the same result. Professor Alport was even offered an increase of salary to silence him. In order to obtain some reform of the nursing service he exposed the scandals in a pamphlet, which he had difficulty in circulating, and now in this book. Personal attacks were made on him by the university authorities when they found that they could not shut his mouth. Thus they have not only done nothing to abolish the scandalous ill treatment of the patients in hospitals but have actively supported it. Here is a country the heir to one of the oldest civilizations in the world which has successfully adopted much of European civilization, including modern hospitals, yet treatment is allowed to be reduced to a farce by the corrupt practices of the nurses.

Laboratory Investigations in the Diagnosis of Virus Infections

Discussing laboratory investigations in the Chadwick Lecture, delivered at the Royal Society of Tropical Medicine and Hygiene, Professor S. P. Bedson complained of the delay in the findings of research passing into everyday knowledge. Much of the work of the past fifteen years had gone unnoticed, and insufficient use was made of the diagnostic procedures which virus research had made available. It was still widely believed that all viruses were too small to be seen with the microscope, yet in quite a number of virus diseases microscopic demonstration of the causal agent was of diagnostic value. This held for trachoma and for conditions due to the nearly related virus of inclusion conjunctivitis. The virus of lymphogranuloma venereum could at times be demonstrated in smears made from inguinal buboes, which occurred in many cases of infection with this virus. Recent work had demonstrated the diagnostic value of smears made from the skin lesions of smallpox. Even when demonstration of the virus by the microscope could not be achieved, histologic changes, such as inclusion bodies, could be looked for. They were always suggestive of a virus infection, and in certain instances, such as the Negri body in rabies, they were diagnostic.

Valuable though microscopy might be in the laboratory investigation of virus disease, as in any infection, the aim of the laboratory should be the isolation and identification of the causal agent. In the case of viruses this entailed the injection of experimental animals or eggs and establishing the viruses preparatory to their study. But unfortunately quite a number of viruses affecting man were so specifically adapted to him that it was impossible to grow them apart from human tissues, and even when animals or the egg were suitable the time consumed in identifying the virus made the procedure of little use in immediate diagnosis. Nevertheless, whenever the diagnosis was in doubt attempts to isolate and identify the virus should be made. It was still far from being generally appreciated that the serologic reactions employed in bacteriology were equally applicable to the identification of viruses or the diagnosis of virus disease. Of these reactions the complement fixation test was probably the most valuable for virus work. It could be used either for the demonstration of the causal virus, as in the diagnosis of smallpox, or for the detection of antibody produced in response to infection, as in influenza, psittacosis, lymphocytic choriomeningitis, lymphogranuloma venereum or mumps.

A New Vitamin in Butter

In the laboratories for physiologic chemistry of the University of Amsterdam research has been in progress during recent years under the direction of Professor B. C. P. Jansen on the favorable influence of butter fat on the growth of young rats. Professor Jansen and Dr. J. Boer found that summer butter fat showed a more favorable influence on the growth of young rats than other fats, even winter butter fat. The factor responsible for this action is not identical with any of the known vitamins. The glycerides of the fatty acids from summer butter have, if the unsaponifiable fraction from summer butter is added, a growth promoting action equal to that of summer butter. The factor responsible for this better growth apparently is an unsaturated fatty acid, because the growth promoting action of summer butter fat and of the fatty acids from summer butter fat disappear on hydrogenation. This cannot be due to a diminished food intake or to poor absorption of the fat in the ration having a rather high melting point.

A number of portions of about 2,000 Gm. of methylesters of fatty acids from summer butter were submitted to accurate fractional distillation. The fraction with eighteen carbon atoms which was isolated by fractional distillation of the methylesters of the fatty acids from summer butter appeared to have growth promoting properties; the corresponding fatty acid fraction of the hydrogenated fatty acids did not. Dr. A. J. Kentie, who describes in a recent dissertation these researches, concludes that vaccenic acid seems to possess all the properties mentioned. Vaccenic acid, discovered in 1928, can be produced from Chinese wood oil. Professor E. Brouwer of the Agricultural University of Wageningen has found that the highest concentration of vaccenic acid is in summer butter fat. This explains why the growth promoting factor of summer butter exceeds the growth promoting factor of winter butter. A fraction consisting mainly of vaccenic acid, separated from the fatty acids of summer butter, appeared to have growth promoting properties if added in a concentration of 1 per cent to rapeseed oil. Probably vaccenic acid is one of the growth promoting factors present in summer butter.

New Fees for Dutch Doctors

A large number of mutual assurance foundations exist in the Netherlands which have contracts for the medical aid and assistance of their members with 6,300 Dutch doctors. Only persons with limited revenues can affiliate with such an assurance institute, controlled by the state. Those who are members of a mutual assurance foundation are free to choose or discharge their house doctor. The doctor has to give all medical treatment and aid. Patients can call him at their home whenever they want. Medical treatment by specialists and care in a hospital or sanatorium is also provided by the foundation, if judged necessary by the house doctor.

For all patients who have chosen a special doctor, the doctor was paid a certain annual amount. In the cities a doctor received 4 guilders for adults for a whole year; for children only 1 guilder. A doctor could have up to 2,500 patients affiliated with a mutual assurance company.

Persons with an income higher than the limit fixed by the government and the assurance institutes for affiliating to their foundations had to pay for every visit to their doctor or for every call at their home. The fee is about $1 (it takes 2.68 guilders to equal a dollar).

The contracts by the 172 existing mutual foundations with the doctors was fixed long before the war. But during and after the war the limit of revenues for those who wanted to become affiliated with an assurance foundation were raised from 2,200 guilders to 3,000 guilders and recently to 3,750 guilders a year ($1,500). The raising of the income level was explained by the fact that many persons who could afford to pay their doctor for every treatment before the war, were no longer able to do so because of the increased cost of living.

For the doctors the raising of the income level meant that fewer persons than before were now paying for every treatment, the income of the doctors thus decreasing. Therefore the 6,300 doctors who had contracts with the assurance foundations gave warning of ending their existing contracts on Nov. 1, 1946, saying that the rising cost of living required them to ask for new contracts with better conditions. They continued, however, to give their medical assistance to all their patients.

After negotiations by representatives of the government, the Dutch doctors and the assurance institutes, new contracts for doctors and specialists were fixed on January 20. During 1947 the doctor will receive 4.68 guilders for each patient who chooses him as physician. After 1947, 4.25 guilders will be paid. The fee for children will be equal to that for adults. Although the doctors are not fully satisfied, they hope that living conditions for themselves will be better than before.

Death of Professor van der Wielen

The death was announced of P. van der Wielen, emeritus professor of pharmacy. During his long tenure van der Wielen earned a great reputation. He lectured on pharmacy both to the candidate apothecaries and to medical students. He contributed in many publications to the methods of drug control and pharmaceutic chemistry. In several volumes he commented on the Netherlands Pharmacopeia. One of his services to the medical profession consisted in the joint editorship of the Pharmacotherapeutisch Vade Mecum, whose other editor was Dr. Pinkhof, a victim of the Nazi occupation. This handy book is a compilation of descriptions of almost all available drugs and pharmaceutic preparations, with concise comments on their chemical, pharmacologic and toxicologic properties and suggestions as to their clinical application. This vade mecum has reached many editions and it was kept up to date. There are few practitioners or specialists who do not keep this book close at hand to afford them information on drug therapy. The reliability of this information greatly adds to the safety of therapeutic measures in this country.

International Congress for Orthopedic Surgery and Traumatology at Amsterdam

In September 1948 an international congress for orthopedic surgery and traumatology will be held at Amsterdam. Dr. Henry W. Meyerding of the Mayo Clinic will be chairman of the congress.

SWEDEN

(From Our Regular Correspondent)

STOCKHOLM, March 18, 1947.

New Mental Hospitals

As previously mentioned, the Royal Swedish Medical Board has drawn up a five year plan for the building of new hospitals and the general improvement of the socialized medical service in Sweden. Included in this plan is a proposal for the construction of two special mental hospitals, intended for those sentenced by the courts to psychopathic care and those coming from social welfare institutions, such as alcoholic addicts. As the situation now stands, persons "sentenced" to mental care are sent to special divisions of the insane asylums. The disadvantages of this system are self evident. The patients themselves feel degraded and the institutions have a difficult time taking care of them in that special safety measures must be taken to keep them from running away and so on. These patients do not belong in an ordinary insane asylum, and the medical board, aware of the need for improving the situation, has proposed the construction of two hospitals, preferably in the neighborhood of large industrial towns. Some sort of employment in industry would promote readjustment into society. By building small pavilions and independent "boarding houses" as part of the institutions, the patients could adjust themselves gradually to society, thus eliminating the dangers inherent in a sudden change from a sheltered to a free life.

These new hospitals are still on paper and will be a long time in maturing to reality. Owing to the need for general hospitals, especially in consideration of the health insurance reform of 1950, which will send even more people into the hospitals, it remains to be seen where on the list of new construction these mental hospitals will stand.

Report of Study of Day Nurseries

Sweden has a number of state aided day nurseries for children in large cities throughout the country, not nearly enough for the demand, of course, but relatively more than exist in the United States. A social welfare investigating committee recently made a disturbing report on the incidence of disease in these nurseries. On the basis of a study made of one of the Stockholm nurseries last fall, it was stated that the condition of the children's health was not satisfactory. The nursery children were significantly more susceptible to disease than the control group of children who stayed at home, and the number of cases of illness was far greater. Many of the nursery children have had colds for long periods and many have constant fever. Ear infections are far more numerous. Sinus and kidney inflammations have appeared among the nursery children, but not in the control group. Bacteriologic studies revealed that certain types of bacteria, which do not ordinarily appear in epidemic form, have caused minor epidemics at the nursery and that children are hardly recovered from one infection before they contract another or are perhaps infected with several types of bacteria simultaneously. Recommendations were made for the installation of ultraviolet lamps and the impregnation of floors and textiles with oil to reduce the risk of infection. With such a large percentage of Swedish mothers out at work every day, these nurseries are of the utmost importance in the present state of society.

Correspondence

SENSITIVITY TO SULFONAMIDES OR PENICILLIN

To the Editor:—After reading the report of the case reported on page 849 of the March 22 issue of THE JOURNAL, "Reactions to Penicillin," I was impressed with the fact that the case so described as a serum sickness type of reaction to penicillin was, in reality, an acute reaction to sulfathiazole.

According to the history, the patient went through the first stage of thoracoplasty on Aug. 13, 1946. At that time 3 Gm. of sulfathiazole crystals was sprinkled in the wound. On September 8 the second stage was accomplished with 3 Gm. of sulfathiazole crystals again sprinkled in the wound. The untoward symptoms began on the day of surgery. The penicillin had been given for only three days prior to surgery. The time element evidence points to an immediate reaction to sulfathiazole. Serum sickness reactions usually begin seven to ten days after the initial administration.

I have seen several cases like the one described as a result of the surgical use of sulfathiazole cyrstals. The literature is full of febrile reactions, dermatitis and other conditions from the topical application of the sulfonamide powders. In fact, the finger of suspicion points to this practice as a factor in necrotizing arteriolar lesions.

This note is not written to discredit the use of procaine hydrochloride intravenously in the treatment of drug reactions. I feel that this method of therapy is worthy of full consideration. However, one should not call this a serum sickness type of reaction to penicillin without ruling out the possibility of the sulfathiazole being the offender, especially in view of the high sensitizing index of sulfonamides as compared with the relatively low sensitizing index of penicillin.

LEWIS E. ABRAM, M.D., Cleveland.

PROCAINE FOR URTICARIA FROM PENICILLIN

To the Editor:—Concerning the article on the use of procaine hydrochloride in urticarial reactions from penicillin (Dressler and Dwork, THE JOURNAL, March 22), a word of caution should be offered: The effect of this medication in hives is indeed startling and probably excels in efficacy anything else recommended for urticaria. In Europe this method has also been employed on a large scale in the treatment of intractable asthma with remarkable results. It should be borne in mind, however, that sensitivity to cocaine and related drugs is not uncommon (Waldbott, G. L.: So-Called Thymic Death, *Arch. Otolaryng.* **17**:549 [April] 1933). The literature reveals many instances of fatal anaphylaxis when, during administration of local anesthesia, a vein was accidentally punctured and relatively small amounts of the anesthetic were introduced into the blood stream of patients who were sensitive to the drug. I have recently been called to see a patient who had been given approximately 0.5 Gm. of procaine hydrochloride in 250 cc. of saline solution intravenously for the relief of urticaria following the recommendation of State and Wangensteen (THE JOURNAL, April 13, 1946). She developed severe allergic shock and was saved only by the prompt action of the attending physician. Sensitization to the drug is particularly apt to develop in patients with chronic urticaria, since they are liable to have second and third injections of procaine after intervals of a few weeks in a manner similar to the one of producing anaphylaxis in animals. Preliminary skin tests for these drugs are unreliable, especially when the skin is covered with urticarial lesions.

GEORGE L. WALDBOTT, M.D., Detroit.

EFFECTS OF HEXYLRESORCINOL ON SURFACE TENSION

To the Editor:— Please permit me to correct an opinion expressed by Dr. Gilbert J. Thomas in his discussion on page 587 of the March 1 issue of THE JOURNAL. He said "Hexylresorcinol in 1:1,000 solution changed the physical properties of the urine by increasing the surface tension."

I think that if Dr. Thomas was to investigate he would find that hexylresorcinol decreases surface tension. Although the disinfectant powers of this compound have been attributed by some to its ability to reduce surface tension, it is interesting to note that some other surface tension reductants are not as germicidal as hexylresorcinol even though they may produce an equal reduction in surface tension in the concentration used. However, in a *homologous series, surface tension reducing power shows* a definite relationship to bactericidal activity. These facts suggest a specific activity of the hexylresorcinol molecule over and beyond its action on surface tension. Therefore I would say that this compound does not act merely as a physical agent, as Dr. Thomas suggested.

This subject is discussed on page 110 of "A Textbook of Bacteriology" by Zinsser and Bayne-Jones (ed. 8).

HUGH A. INNESS-BROWN JR., Vermillion, S. D.

PROLONGED REACTION TO BENADRYL

To the Editor:—THE JOURNAL has come to occupy a well deserved place as the major, if not the only, medical periodical read by the average general practitioner in this country. This places a heavy responsibility on contributors, as their procedures, technics, dosages and sometimes even minor suggestions may be adopted in toto by a practitioner too busy to investigate further. For this reason it is disturbing to us as pharmacologists to see important fundamental principles overlooked in an article published in THE JOURNAL.

In a communication entitled "Prolonged Reaction to Benadryl" by Samuel Schwartzberg and Darrell Willerson (THE JOURNAL, February 8, p. 393) the authors suggest treatment of a Benadryl reaction with intravenous histamine. This may seem a logical procedure when one thinks of Benadryl only as an antihistamine drug; but drugs, especially those with complex chemical formulas, seldom act on only one system or mechanism. It is probable that most of the toxic reactions to Benadryl involve mechanisms entirely distinct from its antihistamine activity, and injection of histamine might actually be harmful in such cases. Histamine causes dilatation and increased permeability of blood vessels—a picture closely resembling clinical shock. In a case of shocklike reaction to Benadryl such as that described in the same issue of THE JOURNAL by Drs. Geiger, Rosenfield and Hartman, injection of histamine could aggravate the condition, with a possibly fatal outcome.

It therefore seems to us that when the authors made their suggestion, which may be worthy of consideration in their case, they should have added a strong word of caution. The radical therapy proposed should certainly be used only when all provisions are made for handling untoward reactions which might follow. The use of intravenous histamine has no theoretical justification in most reactions to Benadryl.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act: Conflict of Medical Testimony.—The petitioner filed a claim for an award under the workmen's compensation act for injuries sustained in the course of his employment with the Aluminum Company of America. An award in his favor was reversed on rehearing before the commission, so the petitioner appealed to the Supreme Court of Arizona.

In May 1943 the petitioner was struck on the left side of his back, with considerable force, by a 2 by 12 plank, causing an abrasion about 6 inches long. X-rays taken on the day of the accident disclosed no fracture, bone injury or tearing of the tendons or tissues. About a week later, however, additional x-rays showed that the petitioner had a rather old and well developed case of arthritis existing in two forms, hypertrophic and rheumatoid. Following the injury the petitioner suffered from pain, and finally, in July 1943, quit his employment because of his condition. On July 22, 1944 the compensation commission granted an award for temporary partial disability for a period not to exceed sixty months subsequent to June 20, 1944. On rehearing the commission held that the petitioner had no disability resulting from the accident after June 19, 1944 and it therefore set aside its previous award. On appeal to the Supreme Court, the sole question was whether or not the evidence was of such a character as to justify the final finding of the commission.

The parties agreed that petitioner was totally disabled because of pain resulting from rheumatoid arthritis and that at the time of the accident the petitioner was suffering from both hypertrophic and rheumatoid arthritis. The medical experts agreed that petitioner's disability as of June 1944 had no relation to the hypertrophic form of arthritis; that the infectious or rheumatoid arthritis is progressing; that the accident did not cause or bring on the rheumatoid arthritis; that hypertrophic arthritis is a chronic generally nondisabling disease or condition of the joints indicated by bony spars or spurs at the site of the attachments of tendon, fascia or ligament and usually due to continued irritation or strain; that rheumatoid arthritis, on the other hand, is "a chronic disease of the joints . . . marked by inflammatory changes in the synovial membranes and articular structures and by atrophy and rarefaction of the bones," is of an infectious character, produces inflammation, and is characterized by pain.

Some of the medical experts testified that the rheumatoid arthritis at the time of the accident was latent in character, and that the accident caused it to flare up, or that it was aggravated by the injury. They took the position that, since petitioner was not disabled by the disease at the time of the injury but became disabled shortly thereafter, the injury was the activating cause of the pain and therefore the disability was produced by the accident. Approximately an equal number of other medical experts testified, however, that, there being no tearing of ligaments, tendons or tissues or fracture of bones, the injury was not severe enough to light up or activate the existing disease. It was the position of these doctors that the disease condition of petitioner's spine on the date of the accident made it more susceptible to pain than would be a normal spine and in addition that the pain resulting from the accident might therefore continue for a longer period than if the spine were in a healthy condition. It was their theory that petitioner's condition as of June 1944 must be attributed solely to the progress of the disease itself and not in any way to the accident.

It appears, said the Supreme Court, that the different theories of the medical experts are based on what would seem to be not only admitted facts but reasonable hypotheses. Whether the rheumatoid arthritis was permanently activated by the injury is largely a medical question. It would also seem to be largely a matter for expert medical opinion when the effects of an injury to a diseased spine would subside and whether the pain and consequent disability as of a year after the accident was from the effects of the injury itself or was a result of the progress of the disease. In a prior Arizona case the rule has been established that where the determination of a question of disability must rest on expert medical testimony, and the opinions of the experts are based on supporting facts and logical theories, this is reasonable evidence for the commission's consideration. Here, pointed out the Supreme Court, the evidence is conflicting. The commission might have followed either of the theories advanced by the medical witnesses. Since the opinions of the medical experts which were apparently followed by the commission conformed to the rule of the cases mentioned, the Supreme Court concluded that it could only affirm the award. Accordingly the award in favor of the petitioner was affirmed.—*Lewis v. Industrial Commission, 173 P. (2d) 639 (Arizona, 1946).*

Pharmacists: Liability for Error in Filling Prescription.—The defendant, a licensed pharmacist, in filling a physician's prescription calling for the delivery of 21 grains of sulfathiazole, in powder form, misread the written prescription and delivered 147 grains in tablet form; and the purchaser consented to grind the tablets into powder. As a result of the defendant's error the patient for whom the drug was intended, an 8 months old infant, was given doses containing 21 grains of the drug whereas the prescription called for doses of 3 grains. After the ingestion of six doses the baby died. The defendant was indicted on two counts: (1) manslaughter in the second degree and (2) violation of section 1742 of the Penal Law prohibiting the delivery of a larger quantity of drugs than was prescribed. The trial court found the defendant guilty on both counts and the defendant appealed to the supreme court, appellate division, second department New York. The court said that the evidence established that the defendant made a mistake in reading the prescription but that it failed to establish any culpable negligence within the contemplation of the manslaughter statute. Accordingly the verdict of guilty on the first charge was set aside and the verdict of guilty on the second charge unanimously affirmed.—*People v. Greenwald, 65 N. Y. S. (2d) 193 (New York, 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, April 19, page 1239.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various centers, June 16-18. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 131 Riverside Dr., New York 24.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Neurological Surgery: Oral. Chicago, June 4-5. Sec., Dr. Paul C. Bucy, 912 S. Wood St., Chicago.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: Philadelphia, June 15-19. Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: Part I. St. Louis, May 1-2. Part II. Chicago, Jan. 22-23. Final date for filing applications is Sept. 15, 1947. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pediatrics: Effective May 1, application fee will be $125.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Robert H. Ivy, c/o Clerical Secretary, 4647 Pershing Ave., St. Louis 8.

American Board of Psychiatry and Neurology: New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

American Board of Surgery: Final date for filing application for the next written examination is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

45:1-122 (Jan.) 1947

Epidemiology of Terminal Bronchopneumonia: I. Significance of Postmortem Cultures in Determination of Etiology of Terminal Pneumonia. W. G. Smillie and Dorothy R. Duerschner.—p. 1.

Id.: II. Selectivity of Nasopharyngeal Bacteria in Invasion of Lungs. W. G. Smillie and Dorothy R. Duerschner.—p. 13.

Salmonella Types Encountered by the 15th Medical General Laboratory. D. W. Bruner and B. J. Joyce.—p. 19.

Susceptibility of Different Species of Avian Malarial Parasites to Drugs. E. H. Dearborn and E. K. Marshall Jr.—p. 25.

Further Studies on Stability of Resistance to Common Cold: Importance of Constitution. F. Sargent II, Olive M. Lombard and Virginia W. Sargent.—p. 29.

Epidemiologic Aspects of Outbreak of Infectious Hepatitis. R. E. Trussell.—p. 33.

Effect of Four Different Therapies on Relapse Rate of Vivax Malaria. W. Trager, F. B. Bang and N. G. Hairston.—p. 43.

Isolation of Typhus Rickettsiae from Rat Mites Liponyssus Bacoti in Peiping. Wei-T'ung Liu.—p. 58.

Physiologic Factors Which Influence Infection of Aedes Aegypti with Plasmodium Gallinaceum. W. Hovanitz.—p. 67.

*Serologic and Epidemiologic Studies on Primary Atypical Pneumonia and Related Acute Upper Respiratory Disease. M. D. Eaton and W. van Herick.—p. 82.

Effect of Vaccination on Incidence of Influenza B. G. K. Hirst, A. Vilches, O. Rogers and C. L. Robbins.—p. 96.

Prolonged Storage of Human Pathogenic Protozoa with Conservation of Virulence: Observations on Storage of Helminths and Leprospiras. D. Weinman and Joan McAllister.—p. 102.

Primary Atypical Pneumonia.—On the basis of antigenic composition, host range, pathogenicity and other properties, Eaton and van Herick point out that the virus of atypical pneumonia is distinct from the viruses of influenza A and B, the viruses of the psittacosis group, the pneumonia virus of mice and the common nonbacterial infectious agents of the respiratory tracts of cotton rats and hamsters. Their results permit a more accurate evaluation of the etiologic relationship of the virus to epidemic and sporadic acute respiratory disease with or without pneumonia. Virus neutralization tests were done with paired acute phase and convalescent serums from 213 persons with various types of respiratory disease. Significant increases in titer of fourfold or greater were found in the serums of 52 of the 84 persons with primary atypical pneumonia and in the serums of 15 of the 77 with undifferentiated upper respiratory infection. As controls, 52 pairs of serum specimens from persons with respiratory diseases were also examined. Only one, the serum of a patient with type A influenza, showed a fourfold increase in neutralizing antibodies. Nearly all persons having primary atypical pneumonia with positive cold isohemagglutinations and with significant titers of agglutinins for the indifferent streptococcus number 344 also had definite increases in virus neutralizing antibodies. In four localized epidemics of acute respiratory illness associated with pneumonia occurring in 1941 and 1942 a high proportion of the cases showed positive neutralization with significant increase in titer of antibodies for the atypical pneumonia virus. Agglutination of streptococcus number 344 was found in about half the cases in the two outbreaks among civilians and in less than 10 per cent of the cases in the other two outbreaks, which were at army camps. The acute phase antibody levels in persons with atypical pneumonia or upper respiratory infection and positive virus neutralization were, on the average, lower than in those who had other respiratory diseases with negative virus neutralization.

213:1-128 (Jan.) 1947

Migrainous Personality and Constitution: Essential Features of the Disease; Study of 500 Cases. W. C. Alvarez.—p. 1.

*Fatal Infection with Poliomyelitis Virus in Laboratory Technician: Isolation of Virus from Lymph Nodes. H. A. Wenner and J. R. Paul.—p. 9.

Gynecomastia Due to Malnutrition. G. Klatskin, W. T. Salter and F. D. Humm.—p. 19.

Mild Rheumatic Reaction in Coast Guard Recruits. H. Poliakoff.—p. 37.

Blood Pressure Studies in 100 Cases of Coronary Occlusion with Myocardial Infarction. W. N. Chambers.—p. 40.

Specific Dynamic Action as Means of Augmenting Peripheral Blood Flow: Use of Aminoacetic Acid. R. Gubner, J. R. Di Palma and Elizabeth Moore.—p. 46.

Evaluation of Immune Serum Globulin as Prophylactic Agent Against Homologous Serum Hepatitis. G. G. Duncan, H. A. Christian, J. Stokes Jr., W. F. Rexer, J. T. Nicholson and A. Edgar.—p. 53.

Pathology of Experimental Frostbite. N. B. Friedman, K. Lange and D. Weiner.—p. 61.

Use of Posterior Pituitary Extract (Pituitrin) to Measure Renal Function. S. F. Horne and L. M. Morris.—p. 68.

Thiouracil in Thyrotoxicosis: Results of Prolonged Treatment in 35 Cases. E. Rose and Jeannette McConnell.—p. 74.

Relationship of Bromsulphalein Retention to Fever of Natural P. Falciparum Malaria. T. E. Machella, with technical assistance of R. Fine and D. Burgoon.—p. 81.

Rheumatoid Arthritis. A. D. Wallis.—p. 87.

Diagnosis of Pulmonary Disease. L. L. Friedman.—p. 97.

Personality Repercussions of Anterior Poliomyelitis: Review of Literature. C. E. Stanfield.—p. 109.

Psychosomatic Relationships in Acute Anterior Poliomyelitis. F. G. Ebaugh and C. S. Hoekstra.—p. 115.

Fatal Infection with Poliomyelitis Virus in Laboratory.—Wenner and Paul report a fatal case of poliomyelitis which occurred in a laboratory worker. It is probable, although not definite, that this man acquired his infection as a result of exposure to poliomyelitis virus in the laboratory. Prior to his infection he was working with human infectious material and with strains of poliomyelitis virus in their early monkey passage. Poliomyelitis virus was isolated from the throat (during life) and at necropsy from the central nervous system, the washed wall of the duodenum, mesenteric lymph nodes and some of the right axillary lymph nodes. Just prior to his illness he sustained an injury to his skin on the right wrist.

Rheumatoid Arthritis: Diagnostic Significance of Focal Cellular Accumulations in Skeletal Muscles. G. K. DeForest, H. Bunting and W. E. Kenney.—p. 40.

Diagnosis of Guillain-Barré's Disease. J. R. Brown and A. B. Baker.—p. 45.

Agranulocytosis Caused by Thiouracil: Review of 59 Cases in Literature and Report of 2 Additional Cases. J. H. Morton.—p. 53.

Penicillin Therapy of Scarlet Fever and Streptococcus Carrier.—Jennings and DeLamater present an extensive bacteriologic and clinical study of an epidemic of streptococcic disease, including scarlet fever, which was caused by a sulfadiazine-resistant strain of group A, type 17, hemolytic streptococcus. The epidemic occurred in young men of military age. A comparison of the complication rates shows complete parallelism with the relative severity of each clinical entity, the rate being highest for scarlet fever and lowest for "nasopharyngitis." Comparison of the clinical response to penicillin and sulfadiazine shows sulfadiazine to be ineffective and penicillin to be dramatic in its relief of symptoms.

Truncus Arteriosus in Infancy.—Of 2 infants with truncus arteriosus, 1 had bronchial arteries and showed intense cyanosis; the other, whose arteries arose directly from the aorta, did not have cyanosis. In both infants the contour of the heart in the left anterior oblique position was identical. In each infant the right ventricle extended out abruptly from the aorta to the anterior chest wall as a shelf. At necropsy the structures of the ventricles and their relation to the truncus arteriosus were found to be identical. Therefore Taussig believes that this contour is characteristic of a truncus arteriosus in infancy in which the ventricles are normally formed and in which the aorta overrides the ventricular septum and receives blood from both ventricles.

Effect of Explosive Decompression on Cerebrospinal Fluid Pressure. W. V. Whitehorn, A. Lein, A. Edelmann and F. A. Hitchcock.—p. 253.

Nutritive Value of Fats with Sucrose or Lactose.—Ershoff and Deuel report observations on male and female rats which were fed diets containing 70 per cent sugar (lactose or sucrose) and 30 per cent fat (butter fat, margarine fat, corn oil or cottonseed oil). When lactose was the dietary carbohydrate, survival was significantly longer on rations containing margarine fat or butter fat than on diets containing corn oil or cottonseed oil. With sucrose as the dietary carbohydrate, no significant differences in length of survival were observed. Male and female rats were fed diets consisting of a single fat. With female rats of the U. S. C. strain, length of survival was longest with butter fat as compared with lard, olive oil, corn oil, margarine fat, soybean oil, wheat germ oil and cottonseed oil groups. With females of the Sprague-Dawley strain, results on butter were significantly better than with margarine fat, corn oil or cottonseed oil. Significant differences in length of survival were not observed in male rats fed these fats. Periods of survival of male rats on sugar-fat mixtures as well as on exclusive fat diets were longer than those of female rats.

Thiamine Deficiency and Diet High in Carbohydrate.—Ring says that the specific dynamic action of a diet high in carbohydrate and containing adequate thiamine is about twice as large as that of a similar diet without thiamine. He found that 1 mg. of thiamine added to a kilogram of this diet did not produce as large a specific dynamic action as 2 or more milligrams.

Blood Carboxyhemoglobin Concentration and Hypoxia.—According to Pitts and Pace the carbon monoxide concentrations which obtain in some aircraft may lead to concentrations of at least 12 per cent carboxyhemoglobin in the pilot's blood under operating conditions. For military reasons a study was initiated on the effects of such blood carboxyhemoglobin concentrations at intermediate altitudes where airborne personnel do not ordinarily use oxygen breathing equipment but, nevertheless, suffer reduced arterial oxygen saturations. Studies were made on a group of 10 normal men. On the basis of the changes in pulse rate it was possible to derive a quantitative estimate of the effect of blood carboxyhemoglobin on hypoxia tolerance. The increment in response to 1 per cent increase in blood carboxyhemoglobin was equal to that obtained by raising a normal group 335 feet in pressure altitude. This value was determined for the altitude range of 7,000 to 10,000 feet and for increases in blood carboxyhemoglobin of at least 13 per cent.

Report of Chairman of Executive Board of American Public Health Association to Governing Council 1945-1946. A. Wolman.—p. 59.

Rhus Dermatitis.—Turner says that preventive hygiene and attempted desensitization have not proved effective in preventing rhus dermatitis. The effectiveness of two new chemical herbicides, ammonium sulfamate and 2-4 dichlorophenoxyacetic acid, which have just come into use, provide the first really promising solution of this public health problem. Health department leadership and the cooperative efforts of community agencies can reduce the now prevalent dermatitis to a relatively rare illness.

Control of Air Borne Infection.—The Subcommittee for the Evaluation of Method of Control of Air Borne Infections has summarized its group judgment on the control of air borne infections. The oiling of floors, blankets and bedding has now developed to the point of practical application in the suppression of dust. Such measures reduce bacterial contamination of the air, but there is as yet insufficient evidence that they prevent disease. Dust suppression should be applied wherever practicable in conjunction with ventilation, ultraviolet irradiation and disinfectant vapors. The available evidence strongly indicates that methods of air disinfection (ventilation, ultraviolet irradiation and glycol vapors) are useful adjuvants to aseptic technics in the reduction or elimination of air borne infections in operating rooms and in contagious disease and pediatric wards. It is not yet possible to compare the relative efficiency of ultraviolet irradiation and glycol vapors. The general use of ultraviolet irradiation or disinfectant vapors in schools, barracks and specialized industrial environments is not justified at the present time. There is no justification for the indiscriminate use of ultraviolet light or other methods for disinfecting air in homes, offices or places of public congregation.

Fundamental Principles in Application of Cineroentgenography as Auxiliary Method to Roentgen Diagnosis. J. Moretzsohn de Castro.—p. 103.

Simple Spontaneous Pneumothorax.—A history of physical exertion preceded the onset of spontaneous pneumothorax of only 7 of 24 patients with spontaneous pneumothorax. In 2 instances it followed the throwing of a baseball and snowball respectively and in 3 instances spontaneous pneumothorax followed exertion while in an awkward position. In the uncomplicated cases the acute symptoms usually subsided in a few days, and the time for complete reexpansion of the affected lung varied from one to eight weeks. Nine patients experienced a recurrent pneumothorax. The present day treatment of recurrent spontaneous pneumothorax is either by the production of a chemical pleuritis or by surgical intervention.

Determination of Radium Content of Human Body to Prevent Radium Poisoning. — An integrating gamma ray method was worked out which allows for determining quantities of radium of the order of 0.1 microgram in the body with a fair degree of accuracy within one hour. Amounts of only 0.03 microgram can be estimated within plus or minus 0.01 microgram. Thus, it is possible to detect incipient radium poisoning before the tolerance limit (set at present as 0.1 microgram) is acquired. The double chamber differential method of determining the radon content of expired air samples from persons employed in the radium industry was improved and simplified for routine work.

DDT for Control of Head Lice.—Cowan and his associates say that many requests from school officials and civic organizations were made to the Texas State Department of Health concerning head louse control. Arrangements were made to treat some of the children enrolled in certain schools. The majority of these children were members of large families and lived under crowded conditions. Only volunteers were used, since some children refused treatment. No child having skin abrasions or sores on the scalp was dusted. A dust composed of 10 per cent DDT and 90 per cent pyrophyllite was the insecticide used. The amount of dust applied varied from 2.5 to 5 Gm., the larger quantity being used on girls with long hair. After application of the dust the child was instructed not to wash the hair for one week. At the end of two weeks a second application of dust was made, and a second examination was made to determine the effects of the insecticide on the infestation. A third examination was made at the end of four weeks. At this time only 1 of the 173 treated children had lice, and this child admitted having washed his hair the day after the treatment.

Benadryl in Dermatologic Therapy. F. W. Lynch.—p. 101.

Topical Treatment with Penicillin Ointment.—Wright and Gross treated a variety of superficial dermatoses with penicillin locally in the form of an ointment consisting of 1,000 Oxford units of calcium penicillin per gram in a base of hydrous wool fat and white petrolatum. Patients were instructed to apply the ointment liberally three to four times daily on the infected areas, and in other instances dressings were employed, which were changed twice daily. All patients were advised to keep the ointment continually refrigerated. Twenty-one of 25 patients with impetigo contagiosa were entirely cured within three days. Only 2 of 23 patients with intertriginous dermatitis of the ears responded to topically applied penicillin ointment. Treatment with penicillin ointment failed completely in infectious eczematoid dermatitis, acne vulgaris, monilia, sycosis vulgaris and in patients with varicose, phagedemic, pyogenic and x-ray ulcers. There was an improvement in the condition of 6 patients with furunculosis and 2 patients with carbunculosis, but no cures were effected in this group. Eight patients with ecthyma responded dramatically to treatment, but negative results were obtained in molluscum contagiosum, dermatophytosis and seborrheic dermatitis. The author concludes that penicillin ointment is of value chiefly in the treatment of impetigo contagiosa and ecthyma.

Agranulocytosis Following Intensive Arsenotherapy for Syphilis.—Fisher and his associates report 11 cases in which agranulocytosis occurred during intensive arsenotherapy for syphilis. One case is reported in which this complication occurred in the course of routine orthodox weekly injections of neoarsphenamine. Fifty per cent of the patients had received no previous therapy for syphilis. The reaction occurred in all cases toward the end of the scheduled course of treatment. Immediate cessation of the administration of arsenicals followed, and therapy with dimercaprol, pentnucleotide and liver extract and, in the more severe cases, blood transfusions were instituted. There were no deaths. The cases reported emphasize the importance of a close survey of all patients receiving arsenicals, with particular observation of the temperature and with routine blood counts.

Dicumarol in Multiple Sclerosis.—Putnam and his associates review evidence that sclerotic plaques arise as a result of venular thrombosis. Since Dicumarol (3-3'-methylene-bis-[4-hydroxycoumarin]) seemed to furnish a possible solution for this problem, its administration to patients with multiple sclerosis was begun soon after it became available. It has been administered to a total of 74 patients for periods up to forty-seven months. Patients treated less than six months and those who did not cooperate satisfactorily are disregarded as subjects for study. This leaves 43 for further analysis. Doses of Dicumarol sufficient to raise the prothrombin time to thirty seconds continuously were administered, with constant laboratory control. Twenty-five patients with a remittent form of the disease were adequately treated without interruption. In this group no fresh symptoms or obvious acute outbreaks occurred. Most of the 16 patients with chronic progressive disease continued in their downward course. The treatment of 2 patients was interrupted; they were free from new symptoms while taking treatment, but both had acute relapses when it was discontinued. In 2 patients large doses of Dicumarol failed to produce the expected increase in prothrombin time, and relapses occurred.

Mechanism of Motion Sickness.—Morton and his associates give a summary of studies on the mechanism of motion sickness, which was produced in human subjects by means of a machine designed to reproduce the movements of a ship at sea. Simple pendulum swings were also effective, although some persons susceptible to one motion did not succumb to the other. Vertical acceleration and deceleration in the long axis of the body with head erect appeared to be the most important element in the production of motion sickness. An increase in the frequency of oscillation resulted in a higher incidence of sickness within the limits of the experiment. There was a definite correlation between history of motion sickness and susceptibility on the machines. Electrocardiographic studies, determinations of sugar, phosphorus and other bases in the blood, studies of gases in the arterial blood and so on revealed no significant changes in connection with motion sickness. It is probable that the most important factor in motion sickness in man is stimulation of the utricles by linear accelerations in the vertical plane of the head.

Atrophy of Optic Nerve After Hemorrhage.—A man aged 34, during a massive hemorrhage from a duodenal ulcer, experienced partial atrophy of the optic nerve in one eye, with later development in the other eye. Repeated determinations of the blood count and the blood pressure revealed a persistent peripheral circulatory failure and such an extreme acute anemia that Levatin considers ischemia the chief etiologic factor.

Ocular Changes in Blood Dyscrasias.—The ocular changes occurring in the blood dyscrasias involve principally the optic disk, retinal vessels and retina in the form of edema, hemorrhages and venous distention. The degree of anemia generally determines the type and extent of the ocular involvement. Exophthalmos is the prominent ocular manifestation in diseases in which the abnormal process occurs in the orbit or involves the bones of the orbit. Tassman describes a case of erythrocytosis with ocular changes which was probably toxic in origin and was of temporary duration. A case of hyperchromic anemia (pernicious anemia) with ocular changes is presented. Four cases of leukemia with ocular changes are summarized. A case of Banti's syndrome with profound anemia and changes in the retinas and both optic nerves is reported.

*Congenital Hypoplastic Anemia Associated with Multiple Developmental Defects (Fanconi Syndrome): Report of Case. S. Estren, J. F. Suess and W. Dameshek.—p. 85.

Folic Acid in Pernicious Anemia.—Folic acid in daily doses of 15 to 50 mg. orally or 20 mg. intramuscularly usually produced a submaximal reticulocytosis in patients with pernicious anemia. In 3 patients the hemoglobin and red cells rose to a level of about 12 Gm. and 4.3 million respectively without further rise after three months of therapy. Folic acid in these doses failed to prevent the development or progression of neurologic symptoms indicative of subacute combined sclerosis. In 5 patients folic acid in doses of 5 or 10 mg. orally daily combined with ½ unit of liver extract injected intramuscularly daily produced a reticulocytosis greater than that anticipated from adequate liver extract therapy alone. With combined liver extract and folic acid therapy there was evidence of improvement in the symptoms and signs of subacute combined sclerosis in 3 patients. Folic acid combined with ½ unit of liver extract was found to produce a complete hematologic remission.

Hookworm Anemia.—According to Stransky and Quintos ancylostomiasis is widespread in the Philippines. Their cases were observed in the medical and pediatric wards of the Philippine General Hospital in Manila. They found three types or stages of blood changes. The third of these is an irreversible type, an aplastic anemia. The pathogenesis is obscure, but the authors believe that it is due to bone marrow exhaustion following continuous blood loss in the presence of various factors, including dietary deficiency. The symptomatology and the hematologic and bone marrow findings are described.

Congenital Hypoplastic Anemia Associated with Developmental Defects.—Estren and his associates describe an example of Fanconi's syndrome in a girl aged 11. They believe that this is the first case of this type reported in the American literature. Hypoplastic anemia was associated with pigmentation of the skin, deafness, congenital heart disease and congenital deformities of the thumbs and forearms. There was no response to liver and iron therapy. Three transfusions of blood totaling 700 cc. were given and had little effect. Because the patient was going progressively downhill, and because splenectomy has occasionally given beneficial effects in hypoplastic anemia, removal of the spleen was undertaken. The patient's convalescence was uneventful. One month postoperatively there were no essential changes in the neutrophil or platelet counts. It seemed that the patient was able to maintain a higher level of erythrocyte count than before the splenectomy. In view of the absence of a history of a similar disorder in either parent or their families, the case must be regarded as a genetic sport due to chance aberration in one or more of the hereditary genes.

Transthoracic Vagotomy and Peptic Ulcer.—This report by Ruffin and his associates is based on a study of 30 patients at Duke Hospital who have had a transthoracic vagotomy for peptic ulcer. Each patient had a chronic or recurrent ulcer which had failed to respond to previous medical or surgical treatment. One or more operations had been performed on 15 patients. The duration of ulcer symptoms ranged from three to thirty-five years. Since vagotomy, every patient has been relieved of ulcer symptoms and has been able to consume an unrestricted diet without ill effect. The pain was completely relieved immediately after vagotomy. The most constant effect of vagotomy is the reduction or absence of gastric motility. In patients who have had a previous gastroenterostomy, retention and dilatation of the stomach are likely to occur. Decrease in volume and acidity of the gastric secretions usually follow vagotomy. The relief of pain following vagotomy probably is the result of decreased motility rather than a lowering of gastric acidity. The time interval is too short to draw conclusions as to the lasting value of the procedure.

Insulin Test for Intact Nerve Fibers After Vagotomy.—Hollander describes a physiologic test for the presence of uncut vagus nerve fibers in ulcer patients following interruption of vagal stimuli to the stomach. The test is based on the production of a hypoglycemia of 50 mg. per hundred cubic centimeters or lower. Fifteen units of insulin is administered intravenously, and the production of hypoglycemia must always be proved by blood sugar determinations. A fractional gastric analysis is performed to determine whether the resulting vagal stimuli, set up centrally, are able to evoke any secretory response from the stomach. The validity of this procedure is supported by studies on gastric pouch dogs and on patients. A positive response to the insulin test—consisting of a distinct rise in the curve for free acidity of the gastric aspirates, accompanying the production of an adequate hypoglycemia—indicates that some uncut parasympathetic fibers still connect the vagus center in the medulla with the stomach. A negative response is suggestive but not necessarily conclusive proof that all the vagal fibers which pass to the stomach have been interrrupted.

Effectiveness of Enterogastrone in Peptic Ulcer.—Greengard and his associates describe a method for the preparation of an enterogastrone concentrate of uniform potency and suitable for parenteral injection in human subjects. Therapeutic trial on 43 Mann-Williamson dogs and on 58 patients with proved peptic ulcer has demonstrated that the material is probably effective in preventing recurrences during the period of its administration and for an undetermined length of time thereafter. The protection afforded cannot be explained on the basis of the action of enterogastrone in inhibiting gastric secretion, and the true nature of the agent concerned cannot be defined at present.

Vaccination Against Epidemic Influenza B.—Faced with a possible epidemic of influenza and having a small supply of the vaccine, Norwood and Sachs decided to vaccinate several hundred employees in a war industry. Subcutaneous inoculations of 1 cc. of inactivated influenza virus, types A and B, were given to 366 employees at the onset of an epidemic of influenza B. The incidence in the group vaccinated in time for antibody response was 1.94 per cent. In the comparable group of 4,280 unvaccinated employees the incidence was 8.23 per cent. Loss of time due to sickness was 4.4 times as great in the unvaccinated group as in the group vaccinated early enough for antibody response. The evidence indicates a protective effect of vaccination against epidemic influenza B.

Refrigeration in Trauma of the Extremities.—Pernworth shows that employment of cold for tissue preservation with hope for ultimate functional and morphologic rehabilitation is a therapeutic concept distinct from that of its use as an anesthetic preliminary to amputation. Employing only cracked ice without tourniquet, the author found it impossible to produce undesirable freezing effects regardless of the length of exposure. A man aged 56 who sustained a crushing injury of his left leg halfway between ankle and knee was given 500 cc. of plasma on arrival at the hospital, the leg was surrounded with a 2 inch layer of shaved ice from knee to toes, and it was wrapped in rubber sheeting. Ice was replenished every twenty minutes for two hours until a sterile thermometer inserted deep into the laceration indicated a temperature of 46 F. On the following day small areas of dry gangrene appeared on the dorsum of the foot; although the general condition remained excellent, the prognosis for survival of the leg seemed unfavorable. Nevertheless after thorough antiseptic preparation the tibial fragments were reduced manually, transfixed by thin Steinmann pins above and below the fracture and then incorporated in plaster. Refrigeration, which was resumed, afforded perfect anesthesia for this procedure. Seventy-two hours after the accident slight voluntary movement was present in the toes, but cutaneous gangrenous involvement appeared more extensive. Five days after the injury grayish blue areas of questionable viability had become pink, and active refrigeration was replaced by ice bags surrounding the limb. Within two weeks the hard shell-like plaques of superficial gangrene had separated sufficiently to allow their complete removal, leaving areas of healthy granulation tissue. Subsequent progress was uneventful and terminated in full recovery.

Passenger Comfort in Aviation.—Tuttle states that the altitude conditioned plane assures low altitude comfort even when flying at high altitudes. This type of plane will eliminate most cases of discomfort currently being encountered aloft. Because of the smoother air prevailing at the higher cruising levels, and the rapid ascents and descents made possible with this new equipment, airsickness rates should fall perceptibly. The same holds true for ear trouble, which should become practically negligible in the absence of appreciable pressure changes on the drum. Because of the passengers' comparatively low exposure to the effects of altitude the need for administration of oxygen should also become extremely rare. The air transportation industry's adoption of the pressure cabin type of airplane reflects the greatest stride forward ever made in passenger comfort aloft.

Angioscotoma in Prolonged Mild Anoxia.—Smith and his associates tested the peripheral blind area (angioscotoma) of 15 subjects five times during a seven and one-half hour exposure to an altitude of 10,000 feet, simulated in a nitrogen dilution chamber. A progressive and statistically significant increase in the size of the scotoma was observed, which became most accentuated at the end of seven and one-half hours. The results are in contrast with the negative data obtained when psychomotor performance is measured. When extraneous motivational factors are eliminated or minimized (and this is probably true of a visual task), an anoxic effect may become progressively evident with prolonged exposure to even a moderate altitude.

Drugs for Prevention of Decompression Sickness.—Williams and his group found that oral premedication with codeine and aspirin, aminophylline and meperidine in an effort to prevent or alleviate the pain of decompression sickness, failed to influence appreciably the performance of 21 subjects exercising at a simulated altitude of 35,000 feet. These investigators think it unlikely that aminophylline and any well known analgesic drug will be of value in the prevention and alleviation of the pain of decompression sickness when taken as a premedication. This does not rule out the possibility that in cases of severe pain occurring at altitude one of the stronger analgesics such as morphine given hypodermically at altitude might be of value.

Fractures of Neck of Femur.—Boyd and George present the complications and end results of internal fixation of 300 acute central fractures of the neck of the femur. Smith-Petersen nails were used in 285 of the hips, and Knowles pins were used in 15. On the basis of the results obtained the authors conclude that fracture of the neck of the femur has the following prognosis: mortality, 9.3 per cent; poor end result, 28.1 per cent, including ununited fractures and severe arthritic changes; a fair end result, 19 per cent, and a good end result, 43.6 per cent. It appears that the number of patients with severe arthritic changes in the hip will exceed the number with nonunion. The problem of rehabilitation and treatment of patients with severe degenerative arthritic changes may become more important than the treatment of those with ununited fractures.

Vitallium Mold Arthroplasty in Old Fractures of Neck of Femur.—According to Smith-Petersen and his associates vitallium mold arthroplasty has been performed in 42 cases presenting complications of femoral neck fractures during the past seven and one-half years. Mold arthroplasty consists in first creating a joint as nearly perfect, mechanically, as possible and then guiding nature's repair by means of an inert mold and carefully supervised exercises. As applied to the treatment of complications of fractures of the femoral neck, the procedure is varied according to the extent of the degenerative changes; four different types of mold arthroplasty have resulted. These include (1) routine mold arthroplasty, (2) modified Whitman reconstruction operation, (3) modified Colonna reconstruction operation and (4) intertrochanteric mold arthroplasty. Routine mold atrophy is indicated in aseptic necrosis of the head, limited in extent and occurring after union of the fractured neck. It consists in reshaping the head and acetabulum so as to create two congruous surfaces; the "crater" representing the necrotic area is excised down to bleeding bone and, in cases of relatively extensive necrosis, the resulting defect is packed with cancellous bone from the iliac crest. The reshaped femoral head is covered with a vitallium mold and replaced in the acetabulum. The authors also describe the other three types of mold arthroplasty and say that the results were satisfactory in more than four fifths of the cases.

Inhalation Toxicity of Ketene and of Ketene Dimer. H. A. Wooster, C. C. Lushbaugh and C. E. Redemann.—p. 56.

Toxicity of Methyl Chloride.—Smith and von Oettingen present mortality data for several species of animals exposed to methyl chloride in concentrations ranging from 4,000 to 300 parts per million on a schedule of six hours daily per week. If it is assumed that susceptibility of human beings to the lethal effects of methyl chloride is comparable to that of dogs and monkeys, then it is evident that daily exposures to concentrations of 500 parts per million are extremely dangerous even for a period of two weeks or less. At the lower concentrations there appears to be some degree of correlation between development of the central nervous system and toxic effects of methyl chloride. If this is true, human beings may be more susceptible to the toxic effects than any laboratory animals studied. If work in atmospheres contaminated by methyl chloride is unavoidable, the duration of exposure should be cut to a minimum and a maximal interval allowed between exposures. Delayed symptoms and delayed deaths are typical of methyl chloride poisoning.

Urinary Fluoride Excretion Among Men Employed in Alkylation Plants.—Largent points out that in one process for manufacturing high octane gasoline anhydrous hydrogen fluoride is employed as a catalyst. Small leaks in feed lines may give rise to atmospheric contamination in such degree as might cause chronic intoxication of workmen. The average normal urinary excretion of fluorine by man is 0.4 to 1 mg. per day. Largent presents investigation of urinary fluoride content of samples of urine collected from alkylation plant employees. The results of analysis of some 500 samples of urine are given in a table. Only one sample had a fluoride concentration greater than 4 mg. per liter, and in most of the samples the fluoride content was normal or but little above normal.

Penicillin in Beeswax and Peanut Oil.—Hirsh and his associates employed a preparation of penicillin in beeswax and peanut oil which differs from that of Romansky and Rittman in that it becomes fluid at room temperatures about fifteen minutes after it has been removed from the refrigerator. Twenty-seven patients with various infections were treated with doses varying from 300,000 to 600,000 units once or twice daily. The results were similar to those obtained with the use of other preparations of penicillin in beeswax and oil or with equivalent daily doses of penicillin in aqueous solution. The preparation was found to be easier to administer than the preparations made according to the original Romansky formula.

Histamine Antagonists.—Friedlaender and his associates made a comparative study of 4 synthetic histamine antagonists: benadryl, pyribenzamine, antergan and neoantergan. All compounds afforded some protection to guinea pigs against the fatal effects of intravenous histamine. Five to six times the LD 100 of histamine was necessary to kill all animals protected with 3 mg. per kilogram of benadryl or antergan. The same dose of pyribenzamine was able to protect some animals against as much as thirty-five lethal doses, while neoantergan protected some animals against as much as three times this amount of histamine.

Torulosis of Central Nervous System.—The 2 cases of torula infection of the nervous system reported by Hassin presented a similar clinical but a dissimilar pathologic picture. One patient had an encapsulated tumor the size of a hen's egg which displaced the pons and medulla to the right. The other patient had disseminated involvement of the cerebrospinal system, including the cranial nerves, spinal roots and meninges. In both cases repeated routine examinations of the spinal fluid gave essentially normal results, and the course was chronic in case 1 and acute in case 2. In both cases a diagnosis of brain tumor was made and operations were performed. Aniline dyes (toluidin blue, thionin, methyl blue) bring out in a Torula the presence of a capsule supplied with numerous spikes, spines or spicules and also of Torulae deprived of capsules as usually seen when hematoxylin-eosin stain is used (so-called naked Torulae). Single Torulae or small torular foci produce no reactive changes, which however are present around large foci or in their vicinity in the form of large infiltrations. Fragments of Torulae are present within the tuft cells of the choroid plexuses—an additional proof that the function of the choroid plexus is excretory and not secretory.

Tracheal and Esophageal Obstruction Due to Congenital Vascular Ring.—Sweet and his collaborators present detailed reports of 2 cases of the congenital anomaly characterized by a double aortic arch in which they performed operations. The patients were a boy of 3 and a half months and a boy of 9 months If the posterior and right lateral aspects of the esophagus are indented by the larger persistent right aortic arch, the lesser aortic arch, which is the vessel to be divided, will be found on the left anterolateral aspect of the mediastinum The visualization of the main aorta descending down the left side of the vertebral column would corroborate this probability. Obviously, under these conditions the vessel to be chosen for ligation will be best reached through the left pleural cavity. Case 1 illustrates this. Case 2 is a mirror image of case 1. Here there were defects of the left lateral and posterior surfaces of the esophagus caused by the larger left aortic arch. The descending aorta was seen by x-ray in the right chest. The anomalous, smaller, right arch could be reached only through *the right chest*

Penicillin in Diphtheria and Diphtheria Carriers.—Karelitz and his associates administered penicillin to persons acutely ill with diphtheria and convalescent carriers. The results were encouraging in the treatment of 5 convalescent carriers and 6 patients with faucial diphtheria. The presence of diphtheria among prisoners of war and among American soldiers in the European Theater of Operations afforded the opportunity to investigate these problems. The study was undertaken simultaneously in five hospitals. Patients with faucial diphtheria treated with antitoxin and penicillin, the latter injected intramuscularly every three hours until three consecutive negative nose and throat cultures were obtained daily, were rendered diphtheria negative more rapidly than were the patients who received antitoxin and no penicillin. Carriers of virulent Corynebacterium diphtheriae were likewise rendered free from the bacteria by treatment with penicillin. Penicillin applied *locally in the form of nose drops* or as nasal spray was not effective in faucial diphtheria but seemed more promising in the treatment of carriers Penicillin was ineffective in preventing toxic complications of diphtheria but seemed to hasten the clearing and further the development of complications due to pyogenic organisms. Penicillin should not be used as a substitute for diphtheria antitoxin.

Penicillin for Primary Staphylococcic Pneumonia.—Davis and his associates treated 7 children with staphylococcic pneumonia and empyema by giving both intrapleural and intramuscular injections of penicillin One infant died thirty-six hours after admission. Treatment consisted in the administration of relatively large doses of penicillin intramuscularly and directly into the pleural space, and of moderately large amounts of sulfonamide by mouth. Supportive treatment included blood transfusions and maintenance of a good state of nutrition. Patients should be followed closely by x-ray and fluoroscopy and by repeated physical examination. Surgical drainage should be instituted when indicated.

Lobectomy and Pneumonectomy in Pulmonary Tuberculosis.—Sweet says that until May 1945 a total of 27 lobectomies and 36 pneumonectomies had been performed at the Massachusetts General Hospital. He says that lobectomy and pneumonectomy can be performed with a considerable degree of safety in pulmonary tuberculosis. The best results followed pneumonectomy in bronchostenosis and thoracoplasty failure and lobectomy in those patients who might otherwise have been treated by means of thoracoplasty. Extirpative surgery has failed to solve the problem of management of patients with enormous cavities which are of the type not responding to collapse therapy. There is no evidence that, except in certain individual cases, lobectomy is superior to thoracoplasty as far as end results are concerned Because of the practical impossibility of eradicating the entire disease in the majority of patients by extirpation, the most important factor is the resistance of the patient to the disease. Because pulmonary tuberculosis is not primarily a surgical disease, the hope for future progress lies in the possibility that some medicament may be developed which will overcome the invading organism.

Case of Bilateral Hypernephroma.—Senger and his associates describe a case of bilateral hypernephroma in which the diagnosis was confirmed by tissue study of the tumors during life. This case presents the unusual occurrence of a metastatic lesion appearing in the thyroid gland. This is the first case of bilateral hypernephroma in a female, and the second case in which a biopsy has been obtained to prove tumor in the remaining kidney. The literature has been reviewed and summarized to bring the total number of reported cases to 17.

Splanchnicectomy in Hypertensive Patients with Abnormal Pyelograms.—While reviewing pyelographic data on cases of hypertension, Nesbit and Plumb found 16 abnormal pyelograms. These patients subsequently underwent splanchnicectomy and have been followed for a year or longer. All the patients had supradiaphragmatic removal of thoracic eighth to twelfth ganglions and approximately 20 cm. of the splanchnic nerves. Splanchnicectomy resulted in symptomatic improvement in most of the patients, and corresponding lowering of the elevated blood pressures occurred. All the patients had structural abnormalities of the kidneys that were made evident by pyelography; some were bilateral and some unilateral. Splanchnicectomy appears to have caused no improvement in 1 patient whose renal disease was far advanced; she died two months later of uremia. It appears that gross renal disease does not in itself prevent an effective response to splanchnicectomy, but the operation should not be advocated when the prognosis for life is adversely affected by advanced kidney disease.

Hormone Producing Tumor of Adrenal Cortex.—A case of Cushing's syndrome due to an adrenal tumor is reported in which death of acute adrenal insufficiency occurred thirty-six hours after operative removal of the tumor and in which, at necropsy, complete absence of the opposite adrenal gland was found. This is the fourth such case in the literature. From a review of the available literature it is concluded that an increasing number of successful operative removals are being done as the result of better postoperative therapy. The prognosis, however, is still exceedingly grave in the cases associated with Cushing's syndrome, because of the atrophy and insufficiency of the supposedly normal gland.

Asiatic Schistosomiasis.—The case of acute Asiatic schistosomiasis reported by Warren was unique in that an opportunity was afforded to follow the clinical course with repeated sigmoidoscopies and serial roentgenograms from the onset of symptoms to the termination of a course of treatment—a period of sixty days. The characteristic yellowish nodules of the rectosigmoid and upper rectum were shown to have an earlier stage in which they are distinctly red and are smaller and less resistant to the sigmoidoscope than they are in the later course of their development. The diagnostic value of sigmoidoscopy is confirmed. Serial roentgenologic findings are presented that may have represented a reaction of the lung parenchyma to ova or adult worms of Schistosoma japonicum. This case demonstrated the effectiveness of antimony and potassium tartrate (tartar emetic).

Epidemic Diarrhea of the Newborn.—Rubenstein and Foley review 19 outbreaks of epidemic diarrhea of the newborn as reported to the Massachusetts Department of Public Health from 1935 to 1945. Of 768 newborn infants who were exposed during the course of these outbreaks, 258 developed symptoms and 85 died, the case mortality being 33 per cent. The morbidity rates among premature and full term infants were 49 and 21 per cent respectively. The case mortality for premature infants was more than twice that for full term babies. Investigation of nursing technics and methods of formula preparation in nurseries where these outbreaks occurred revealed many inadequacies. Overcrowding, insufficient personnel, general use of a common rectal thermometer and inadequate supervision of formula making were frequently encountered. Laboratory examinations of so-called sterilizing solutions, including alcohol hand solution and thermometer dips, formulas, nipples and other utensils, showed heavy bacterial contamination. The etiology and the mode of transmission of epidemic diarrhea of the newborn are not known, but supervision of nursery room technics and of formula preparation constitutes a factor in the hospital care of newborn infants that merits greater attention from hospital administrators.

Promin in Scleroderma.—Wuerthele reports that in 1938 a woman aged 52 began to notice splinter-like, very tender lines under her nails. In 1942 a lump developed on the ulnar surface of the left arm. Numbness, pain and ulcerations of the second and third fingers of both hands occurred. Treatment with Hytakerol (a fraction of irradiated ergosterol) produced some improvement, but in 1946 examination of the hands showed club-like, purple fingers, contracted and painful. The nails were clawed and adherent to the underlying ulcers. Codeine was needed at frequent intervals for relief. Even air currents caused pain. The hands were entirely useless. At this stage promin jelly (a 5 per cent promin in tragacanth), was applied liberally to the hands three times daily and covered with white gloves. Improvement in pain was noticed after two days. The ulcers stopped oozing and began to dry after one week. No further codeine was needed. The patient could touch her fingers to objects without pain. The subungual ulcers healed entirely. The patient was able to dress and feed herself, to sew, make beds, open doors. Even knocking the fingers against a table did not cause pain.

Extrapleural Pneumonolysis.—The McCains point out that extrapleural pneumonolysis has recently been revived with the use of a new filling material, methyl methacrylate, commonly known as "lucite." After many experiments on animals, Wilson began to apply the procedure to patients with pulmonary tuberculosis. Through September 1946 approximately 60 patients have had this operation at Duke Hospital. Thirty-one of these patients, who were from the North Carolina Sanatorium, form the basis of this report. The authors conclude that extrapleural pneumonolysis with the use of methyl methacrylate spheres as packing material appears to offer a reasonably safe means of selective collapse therapy in a limited group of patients with pulmonary tuberculosis for whom no other method of collapse is possible. The operation is not without risk, the most serious complications being incidental to penetration of the pleural space and tuberculous cavities, and to infection. Means of preventing these complications have apparently been determined. The anterior approach under local anesthesia is less shocking to the patient than the posterior thoracoplasty type approach and is to be preferred.

Blindness and Brucellosis.—Agin thinks that ocular damage due to undulant fever is probably more common than has been considered heretofore. He describes the types of ocular damage attributable to brucellosis and a case wherein vision was totally destroyed. Efforts should be made in eye infections to detect or rule out the presence of a systemic invasion by the organism of undulant fever. In the presence of ocular brucellosis general treatment should be under the guidance of an internist and should consist of chemotherapy with sulfonamides, Foshay vaccine, immune serum and nonspecific protein therapy. Locally the usual procedures for uveal tract infection should be adhered to, including heat, atropinization and protection from excess light.

Protein Hydrolysates and Dextri-Maltose.—Co Tui reviews observation on the effects of his hyperalimentation treatment in 164 intractable cases of peptic ulcer. He gives protein hydrolysate in doses which furnish 0.6 Gm. of nitrogen per kilogram of body weight, and a carbohydrate, usually salt free dextri-maltose, to make up to 50 calories per kilogram. There was complete relief of pain from the first feeding on in 48; in 82 the pain was relieved in one or two days and in 18 from two days to one week. Night pains disappeared in the first three days in 35, and in the first five days in 22. The treatment failed in 16, or about 10 per cent, of the patients. To these failures must be added 18 who were unable to tolerate the mixtures. However, since the feeding of separate solutions was instituted, i. e., the dextri-maltose following the hydrolysates, there have been no failures due to intolerance in over 30 consecutive cases.

Transthoracic Vagus Resection in Peptic Ulcer.—Smith and his associates report the effect of transthoracic vagus resection on the first 50 patients treated by this method at Duke Hospital. Forty-three of the 50 patients have made a complete clinical recovery to date and have been able to consume a full and unrestricted diet without ill effect. The most constant effect of vagus resection is decreased gastric motility. Gastric retention and dilatation are likely to occur in patients who have not had a previous gastroenterostomy. Vagus resection is usually followed by decrease in volume and acidity in gastric secretion. The relief of pain following vagus resection probably is the result of decreased gastric motility rather than decreased acidity. The time interval is too short to draw conclusions as to the permanent value of the procedure.

Wound Healing in Vitamin C Depleted Human Subjects.—Wolfer and his associates had the opportunity to study the effect on wound healing of a prolonged vitamin C deficiency in 9 otherwise normal healthy young men. They found that depletion delays the development of tensile strength in an uncomplicated healing wound from three to five days up to the fourteenth postoperative day. When circumstances for healing are poor, such as in the presence of undue wound tension or diminution in blood supply, this depletion in ascorbic acid is made more evident through gross failure of primary wound healing. The incidence of wound infection under such circumstances suggests the need for ascorbic acid in the tissues for maximum resistance to infection. Human subjects on prolonged ascorbic acid depletion exhibit lack of collagen and reticulum in their healing wounds.

Cotton as Suture Material.—Derbyshire reviews observations on 372 operations in which cotton suture material was employed. There were 17 cases with late complications attributable to the suture material. Of these, 9 were serious and 8 mild. Complications were present more frequently in the earlier than in the later cases in the series, and it is suggested that this may be due to improvement in technic in the later cases as well as to the fact that the use of cotton was finally given up in cases of obvious infection or contamination. While cotton is an excellent suture material, it is not entirely without hazards and has definite limitations.

Adenomas of the Large Intestine and Their Relation to Carcinoma.—This report is based on a study of 1,460 consecutive necropsies in which the entire large intestine was available for examination. Helwig shows that adenomas of the large intestine are true neoplasms. Their incidence increases with age. Adenomas are more common in the white race than in the Negro race. Adenomas are slightly more frequent in men than in women, but single adenomas are more common in women than in men. Multiple adenomas are as common in the fourth decade as in the eighth decade of life in patients who have adenomas. Inflammation, hemorrhage and hemosiderin are commonly observed in the larger adenomas. Adenomas of the large intestine may undergo malignant transition. Both adenoma with malignant transition and carcinoma are more common in the older age groups. Some carcinomas of the large intestine arise directly from the mucous membrane, but the majority develop in adenomas.

Carcinoma of Corpus Uteri.—The series reviewed by Taylor and Becker includes all histologically proved carcinomas of the corpus uteri in patients admitted to the Memorial Hospital, New York, during the fifteen year period from 1926 to 1940. There were a total of 531. The effect of the gross extent of the disease on the rate of cure is shown by the five year end results in five specified groups. Whereas in the first group, in which the uterus was not enlarged, the rate was 66⅔ per cent, it was only 11.2 per cent in the last group, in which carcinoma extended beyond the uterus. The effect of histologic type is shown by the five year end results in three classifications: adenocarcinoma grades 1 and 2, 47.2 per cent; adenocarcinoma grades 3 and 4, 22.8 per cent; adenoacanthoma, 51.3 per cent. For the patients on whom hysterectomy was performed a five year cure rate of 51.1 per cent was shown, while in the group of patients treated only with radiation the figure was 36.8 per cent. The group with treatment limited only to radiation contained, however, more patients in a relatively advanced stage of the disease. The question of whether the cure rate from hysterectomy is increased when radiation is given in addition could not be answered.

Resection of Clavicle.—Shumacker shows that the manner in which the bony defect has been handled after resection of the clavicle has varied. The results of subperiosteal resection and discarding of the segment have been excellent in some cases, but in others regeneration has been slow. It seemed desirable to hasten the process of bony regeneration. With this in mind a small group was treated by filling the periosteal bed with bone chips secured from the excised segment of clavicle. Experiences are reported in 4 cases of clavicular resection in which rapid and complete restoration of bony continuity followed replacement in the periosteal bed of such bone chips.

Perforated Gastroduodenal Ulcer.—Baritell reviews observations on a group of 88 patients who were operated on for perforated gastric and duodenal ulcers with a mortality rate of 1.1 per cent. A technic of operative treatment, consisting in applying an omental patch to the perforation without any attempt at closure, has been applied to 20 patients with uniform success. It is now the routine at the author's service in all cases and is strongly recommended in any patient in whom there is severe edema or induration about the perforation. Rapid diagnosis and therapy together with chemotherapy and the application of sound surgical principles has resulted in a very low death rate for a disease which heretofore has carried a formidable mortality rate.

Biliary Drainage for Relief of Pruritus.—Varco points out that in certain chronic disorders of the hepatic parenchyma or the intrahepatic biliary system intractable itching is an unpleasant feature. Dihydroergotamine controls the pruritus for only a short while. If the abnormal retention of bile salts is the cause of the pruritus, relief from the itching may be anticipated if it is possible to reduce this concentration in the circulation. Intermittent external biliary drainage suffices to attain and maintain prompt and virtually complete relief from this type of pruritus. Seven operations have been performed on 6 patients without fatality. Circuiting the bile to the outside for short intervals daily has sufficed to keep these persons comfortable. Chronic hepatic disease, either hepatitis or cirrhosis, has been the preoperative diagnosis for all these patients. Pruritus associated with acute hepatitis is so frequently a self-limited disease that surgical procedure for its relief would seem unwarranted.

Recurrent Parathyroid Adenoma.—At operation on a man for a parathyroid adenoma a fragment of the adenoma had become transplanted between the strap muscles of the neck. Two years later the patient returned with manifestations of hyperparathyroidism and a recurrent adenoma at the site of the graft. Burk states that recurrence apparently resulted from proliferation of the transplant. The original tumor was a parathyroid adenoma. It presented no characteristics of malignancy except for penetration of the capsule. In the recurrent tumor, however, some of the cells were less typical, there was no encapsulation, and strands of cells were found between muscle bundles. The pathologists are of the opinion that this tumor should not be diagnosed as carcinoma. While there are mild pleomorphic and hyperchromatic changes in some of the cells, the tumor is still of a well differentiated type.

Allowing Young Children to Set Their Own Pace.—Aldrich shows that much of our modern child care is calculated to prevent our youngest generation from "doing its stuff." Infants are hemmed about with strict prohibitions. The author emphasizes the fact that the proposed liberalized or flexible routines, since they are designed to synchronize with infant physiology, make for greater efficiency in the organism. He outlines some of the many ways in which children try to develop through their own mechanisms. He pictures infants as dynamic, purposeful people who, if allowed to progress when they are ready for each step, will become more and more efficient in the art of living.

Epidemics of Poliomyelitis in New Haven.—Wenner made comparative studies on four epidemics of poliomyelitis which occurred in and about the city of New Haven between 1916 and 1943. It was found that a change has occurred in the age incidence of poliomyelitis in New Haven. Prior to 1920 children less than 5 years of age were attacked almost twice as frequently as those aged 5 to 9 and five times as often as older children 10 to 14 years of age. The ratio of cases in these three age groups in 1935 and in 1943 was 1:1:0.7. The seasonal distribution of poliomyelitis during the four epidemics varied slightly. The peak occurred in August or September.

Serum Proteins in Infective Hepatitis.—Martin made serial electrophoretic examinations of the serum proteins in 11 patients (8 males and 3 females) with uncomplicated infective hepatitis. He noted depression of the albumin component, with a corresponding rise of gamma globulin. There was disturbance of the alpha and beta globulin, notably between the fourteenth and thirtieth days. It was greatest in 2 patients the course of whose infections was relapsing. A breakdown in the beta complex was noted in certain serums, but it appeared to have no diagnostic significance. The results obtained are in no way peculiar to infective hepatitis. Similar patterns have been obtained in infective mononucleosis, in lupus erythematosus and in other conditions. They are not, therefore, an absolute diagnostic aid. Their value lies in forming a base line for further studies of the administration of protein fractions in the treatment and in assessing the effect of those fractions, if any, on the plasma proteins.

Myopathy with Spina Bifida. R. G. Paley.—p. 53.

Dietetic Factors in Liver Disease.—Witts emphasizes that disorders of the liver similar to those produced in experimental animals by dietary deficiency occur in man over wide territories of the world as a result of inadequate food supplies. The incidence of juvenile cirrhosis and primary carcinoma of the liver may well come to be regarded as indexes of nutrition. The problem must now be attacked by social engineering rather than medical science. The number of isolated dietary defects which are known to produce disease is already great, but we are not yet able to permute and combine the various factors so as to discover how they reinforce or neutralize one another. It seems unlikely that fortification with individual principles will be as cheap or as effective as a general improvement of the diet. Our knowledge is more likely to be useful in the selection of those natural foods which can be most expeditiously used to increase the biologic value of the diet.

Surgical Aspects of Roundworm Disease.—Barber says that as a surgeon to the native population of Cyrenaica he repeatedly encountered roundworm infection that simulated surgical conditions. Roundworm infection may become of surgical importance not only by causing mechanical obstruction of the small intestine but by producing inflammatory changes. It is usually difficult to distinguish this variety of inflammation. Correct diagnosis will be facilitated if in regions with prevalent roundworm infection the physician will bear that possibility in mind, using also the laboratory methods for investigation. Surgical treatment will have to consider removal of as many worms as possible from the bowel by "milking" them from adjoining loops toward an incision made over their biggest accumulation. At times the prognosis seems to depend to a considerable extent on the thoroughness with which the worms were removed during the operation.

Heart in Rheumatoid Arthritis.—According to Rogen rheumatic fever and rheumatoid arthritis are generally regarded as distinct diseases which have much in common. The possibility of their having a common etiology has often been discussed. As cardiac lesions are characteristic of rheumatic fever, many workers have sought similar lesions in rheumatoid arthritis. The author records the results of a detailed examination of the cardiovascular system in 33 consecutive cases of rheumatoid arthritis in municipal hospitals in Glasgow. Among these only 1 was found to have a cardiac lesion which might have been attributable to the disease. Another patient was found to have neither histologic nor naked-eye abnormalities of the heart at necropsy.

Red Cell Changes in Severe Burns.—Investigation of the morphologic changes occurring in the red cells of 3 severely burned patients revealed that fragmentation of the red cells and microspherocytosis occur within a few hours of the injury.

Microspherocytosis was seen in stained films and was shown to be associated with an increase in the mean corpuscular average thickness. Fragmentation of the red cells was most obvious in the most severely burned patient and was associated with hemoglobinemia and hemoglobinuria. These morphologic changes can be attributed to the direct action of heat on the cells. The maximum effect is immediate fragmentation and destruction. If the damage is less severe, microspherocytosis is produced and the cells are unduly susceptible to the physiologic trauma of the circulation.

*Vitamin A and Bone Growth: Reversibility of Vitamin A Deficiency Changes. E. Mellanby.—p. 382.

Vitamin A and Bone Growth.—Mellanby points out that a deficiency of vitamin A in the diet of growing animals causes widespread nerve degeneration. A cause of this degeneration was suggested when the examination of serial sections of the labyrinth and its capsule revealed that vitamin A deficiency results in a large bone hypertrophy which injures or destroys the nerve fibers and the cells of the spiral ganglion by pressing on the eighth nerve. The chief point of interest in this publication is the study of the reparative or recovery stage of bone growth, especially of the cranial bones, when vitamin A is restored to an animal after a period of deficiency. The addition of vitamin A to the diet of an A-deficient animal during growth brings about a return of osteoclastic and osteoblastic activity to the surfaces where it is normally found. Although vitamin A deficiency causes a general thickening and dysplasia of bone by its effect on osteoclasts and osteoblasts, the method of producing this abnormal state varies, as is shown in the three regions discussed, namely the basioccipital, the periosteal bone covering the labyrinth, and the sphenoid bone in relation to the optic foramen. The recovery changes on adding vitamin A are also different in different cases. The altered shape of bones adjacent to the nervous system may destroy cranial and spinal nerves and exert other harmful effects, but the recovery changes in dysplastic bone on the addition of vitamin A to the diet take place independently of the condition of the adjacent nerve or nervous tissue.

Acute Porphyria.—Jørgensen and With review recent progress in the knowledge of porphyria and emphasize that there is evidence that barbiturates exert a harmful effect on patients with porphyria, even when it is latent. Two cases illustrating this effect are reported.

Rubella as Cause of Congenital Deafness.—Clayton-Jones says that an inquiry has been made in schools for the deaf in England to ascertain whether the association established in Australia between maternal rubella in the first three months of pregnancy and congenital defects, mainly cataract, deaf-mutism and heart lesions, could be confirmed. At one school with 18 children 8 mothers gave a definite and 1 a probable history of rubella in the second to fourth months of pregnancy. In three larger schools a maternal history of rubella in pregnancy was obtained in 11 out of 123 children. Deaf children with a maternal history of rubella were found to have a bilateral, incomplete, inner ear deafness usually fairly uniform throughout frequency range. Difficulty in feeding during infancy was commonly reported, and examination showed a tendency to deformity of the jaw, pigeon chest and atonic musculature; no cataract or heart lesion was detected. Notifications at Manchester show that the rubella epidemic of 1940 was peculiar in involving an unusually high proportion of young women. An attempt should be made to protect pregnant women against rubella in the first four months of pregnancy.

Penicillin in Agranulocytic Angina.—Mackenzie observed a prisoner of war in whom the appearance of the blood film, considered in conjunction with the profound leukopenia, suggested an aleukemic leukemia of the monocytic type; in view of the throat condition, however, the diagnosis of agranulocytosis was preferred. The question then arose whether it was wiser to attempt to raise the polymorphonuclear leukocyte count with pentnucleotide or to attack the infection with penicillin. The patient's rapid improvement in both physical condition and leukocyte count seems to show that the latter course was correct.

Inguinal Hernia. J. C. B. Allen.—p. 8.

Defects in Infants Following Infectious Diseases During Pregnancy.—Swan and his associates say that of 61 children comprising their first and second series they were able to reexamine 49. The most important result of the resurvey was the detection of 4 further cases of deaf-mutism. In 1 patient spontaneous absorption of a cataractous lens had occurred. Many of the children were retarded in their physical development. A fourth series consisting of 25 cases was studied. In 17 instances (1 doubtful) the mother had contracted rubella in pregnancy. In 1 case the mother had suffered also from chickenpox. Fifteen of the babies born subsequently exhibited congenital defects. The abnormalities included cataract, deaf-mutism, heart disease, microcephaly, umbilical hernia, bifid uvula, mental deficiency, epilepsy, speech defect and concomitant strabismus. Thirteen of the 15 mothers had suffered from German measles during the first four months of pregnancy. Of 2 infants that were free from congenital malformations, one mother had suffered from the disease in the first month and the other in the seventh month of gestation.

Control of Plague by Live Vaccine.—Grasset reviews observations made in southern Africa on antiplague immunization with live avirulent vaccine in fourteen plague outbreaks between 1941 and 1944. He stresses the harmlessness of the method, which was evidenced by the absence of untoward reactions in over 40,000 doses used in preventive mass immunizations of European and native populations. The vaccinal reactions were mild. A high degree of specific protection developed rapidly following immunization. A total of 15 cases with 7 deaths were observed among over 24,000 persons immunized during nine bubonic and septicemic, three pneumonic and two mixed bubonic pneumonic and septicemic outbreaks. Protection derived from immunization begins to be effective from the fifth day after inoculation, reaching full benefit toward the tenth day after inoculation. The author concludes that a single live avirulent plague inoculation (1,000 million organisms) with usual antiplague measures realizes a safe, easily applicable, well accepted and efficient mass plague control method in the epidemiologic field conditions existing in South Africa.

*Treatment of Chronic Rheumatism with Organic Salts of Copper. J. Forestier and A. Certonciny.—p. 884.

Organic Salts of Copper in Chronic Rheumatism.—Forestier and Certonciny used a cupro-allyl-thio-urea-benzoate of sodium which contains 19 per cent of copper in 50 cases of various forms of rheumatism. The preparation is administered twice weekly by intravenous injection. At each injection 0.25 Gm. is usually administered, but recently 0.5 Gm. has been given. The total dose in one series of injections varies between 2.5 and 5 Gm. The intervals between series are from one to three months. The intravenous mode of administration is painless, whereas the intramuscular injection is extremely painful. The substance does not exert toxic effects on the liver or kidney or on the blood or the hemopoietic organs or the skin or mucous membranes. Fatigue and loss of weight were observed in some patients at the end of the series but disappeared rapidly. As regards the action of the organic copper compound, the authors say that it acts quicker and better than do the gold salts.

*Diphtheria Carriers: Their Frequency and Treatment. H. Reber.—p. 1275.
Therapy of Agranulocytosis in Tonsillogenic Infection. H. Cadotsch. —p. 1279.

Diphtheria Carriers.—Reber shows that in searching for carriers of diphtheria bacilli the culture medium on tellurite will be a favorable substitute for mediums previously used. In order to detect as many carriers as possible in an isolated community a minimum of three samples must be collected at intervals of two days. If this is done an average of 6 per cent of carriers are detected in an environment that is free from diphtheria. In children between 3 and 6 years of age the number of carriers is double the average; after that it decreases with age, but in every age group some are found. If an epidemic of diphtheria is feared, it is necessary to treat all persons harboring bacilli with the morphologic characteristics of diphtheria bacilli, since there is no reliable and rapid criterion of pathogenicity. On the basis of experiences with various therapeutic methods, the author says that the local application of penicillin is most effective and represents the method of choice in bacillus carriers. Medical treatment has permitted a considerable reduction of the number of tonsillectomies, this operation being performed only when the general condition of the patient requires it, and when the tonsils constitute a focus of infection.

*Mammary Sarcoma in Women. D. Brachetto-Brian.—p. 35.

Mammary Sarcoma in Women.—Brachetto-Brian performed 10,000 pathologic examinations during a period of sixteen years in the Durand and Ramos Mejia Hospital. He found 350 mammary tumors, of which 212 were malignant. Among the 212 malignant ones there were 207 carcinomas and 5 sarcomas, namely a reticulum cell sarcoma with giant cell formation, primary in the breast, in which its rapid growth led to the diagnosis of acute cancer; 1 fibroblastic sarcoma of seven months' duration in a woman aged 30, situated immediately behind the gland, which is included because it was impossible to establish its independence from the gland; 2 cases of secondary adenofibrosarcoma, 1 of them recurrent, both of which had arisen in a "cystosarcoma phyllodes" (Müller) or "giant intracanalicular myxoma of the breast" (Lee and Pack), and a secondary adenofibrosarcoma arising in a fibroadenoma.

*Abdominovenous Direct Transfusion of Ascitic Liquid in Hepatosplenic Cirrhosis. A. Acevedo Olvera.—p. 27.

Transfusion of Ascitic Liquid in Ascitic Cirrhosis.—Acevedo Olvera based this treatment on the facts that (1) in patients with ascitic cirrhosis of the Laënnec or Banti type the plasma proteins are low, whereas the proteins in the ascitic liquid are high, (2) proteins favor liver function and (3) they are absorbable by the peritoneum. He administered the ascitic liquid to 18 patients with that type of ascites. The liquid was injected directly from the abdomen intravenously by means of an apparatus for transfusion without any modification of the ascitic liquid but just as it was found in "free" ascites. The total quantity for an injection was from no definite figure up to 1,000 cc. The total amount administered varied from 2 to 10 liters. In 4 of the 18 patients the treatment began very late in the course of the disease. Five patients were cured; 3 are still under treatment. In the rest great improvement was noted. One of the patients had brucellosis as the cause of his Banti's syndrome. In general the treatment results in improving the opportunity of the patient for a more favorable reaction to the proper medical, biologic, vitamin and physical therapy in modern use as well as to the proper diet. The article is a preliminary report. The author concludes that the treatment is harmless. It improves the liver functions, is economical, is reliable and is indicated only in "free" ascites due to Laënnec's cirrhosis or Banti's syndrome.

Sensitivity of Meningococci to Penicillin and Sulfathiazole in Vitro. A. Lundsteen.—p. 372.

Production of High Titer Tetanus Serum.—In producing tetanus serum Buer has tried a modification of Ramon's method of inoculation. Ramon injects an emulsion of olive oil, lanolin and tetanus toxin or anatoxin, which causes an inflammation infiltrate. The modification consists in the injection of the toxin into an already existing inflammation infiltrate three or four days after the injections of the aforenamed emulsion. By this means the titer has been doubled and multiplied. Titers of up to between 4,000 and 4,800 international units per cubic centimeter have been obtained.

*Adenoma of Islands of Langerhans in Pregnancy. A. W. M. Pompen, C. A. L. Jansen and J. Dhont.—p. 1791.

Therapy of Migraine.—Bartstra says that patients subject to migraine experience great relief if given from 5 to 10 drops of dihydroergotamine three times daily. Equally favorable results were obtained by giving to women tablets containing an extract prepared from fresh testis tissues and to men tablets containing an extract of ovarian tissue. Treatment is begun by giving three times daily two tablets of the testicular or ovarian preparations. It is not known what factor exerts this favorable effect, since the sex hormone isolated from testis tissues exerts no particular influence on migraine. Thus another substance must be responsible. The frequency of the attacks decreases and the unpleasant sensations between the attacks are also favorably influenced.

Adenoma of Islands of Langerhans During Pregnancy.—Pompen and his associates present the history of a woman aged 35 who had hyperinsulinism as the result of an adenoma of the islands of Langerhans. She passed through two pregnancies after she developed the hyperinsulinism and was free from attacks of hyperinsulinism during the first of these pregnancies and during the second half of the second pregnancy. The attacks returned on the thirteenth and ninth days respectively after childbirth. It is suggested that the glycotropic or anti-insulin factor may play a part. Recent investigations indicate that this activity might be ascribed also to the corticotropic hormone. The hypophysis is thought to produce this substance in abundant quantities in the course of pregnancy.

Experimental Histologic Studies on Labyrinth: X. Supplementary Remarks Concerning the Phenomena of Compression Observed on Intravital and Postmortem Fixation. S. H. Mygind and D. Dedering. —p. 609.

Rheumatic Facial Paralysis.—Bergström says that until recently the treatment of rheumatic facial paralysis, commonly called Bell's palsy, has consisted almost exclusively of simple physical treatments. However, since paresis and contracture or even total paralysis may develop after this conservative treatment, surgery is now being resorted to. A woman aged 35, who had had facial paralysis of the peripheral type on the right side for fifteen years, was cured by surgical intervention. In the course of a decompression operation a section of the facial canal was found to be contracted, which condition is assumed to have contributed to the paralysis. The author thinks that, since spontaneous healing takes place in most cases, operation should not be considered until four months has elapsed without signs of improvement.

Ear Symptoms in Louse Borne Typhus.—Observations on 800 cases of typhus revealed to Mérei that impairment of hearing occurred in from 60 to 65 per cent of the cases, usually in the early stage of the disease. Gradual recovery began after three weeks. As regards the vestibular system, the author says that ataxia with vertigo appeared in about 40 per cent of the cases. The vertigo was not due to fever. Past pointing, ataxia and spontaneous falling often were present up to the end of convalescence. Nystagmus appeared in from 6 to 8 per cent of the patients. The symptoms indicating involvement of the vestibular apparatus appear so early that they can be accepted as a reliable diagnostic sign for typhus.

Hygiea

Nucleotide Metabolism of Dentine Cells Under Normal Conditions and in Vitamin C Deficiency. Å. Wilton and B. Thorell.—p. 1784.

Relation of Renal Tuberculosis to Primary Tuberculous Infection.—Ustvedt states that in over two thirds of 292 cases of renal tuberculosis treated during the last ten years the time between the primary tuberculous infection and the appearance of the renal tuberculosis was more than five years. Renal tuberculosis only occasionally represents disease of the isolated organ; it is more often a link in tuberculosis as a general disease. It manifests itself much later in the course of the tuberculous infection than most other tuberculous manifestations, is often preceded by one or more other localizations of tuberculosis and is not infrequently followed by other tuberculous involvement. It may be present a long time before clinical symptoms appear, and moderate changes may be stationary for years. Much of the pathogenesis of renal tuberculosis is uncertain. Various facts support the American and French conception of bilateral start of the disease with multiple foci localized in the cortex.

*Congenital Hyperplasia of Islets of Langerhans with Increase in B Cells in Fetuses of Diabetic Mothers. G. T. Hultquist, Inga Lindgren and J. B. Galgaard.—p. 1841.

Congenital Hyperplasia of Islets of Langerhans in Fetuses of Diabetic Mothers.—Hultquist and his associates report 4 cases of pregnancy in diabetic mothers with death of the fetus immediately before or during delivery. In 1 instance the mother's carbohydrate tolerance improved during the last months of the pregnancy; in all cases the blood sugar rose after delivery or intrauterine death of the fetus. Microscopic examination of 3 of the fetuses showed hyperplasia of the islets of Langerhans, and study by silver impregnation revealed increase in the B cells in proportion to the number of A cells. There was fatty degeneration of the liver and less severe degeneration of the kidneys, together with increased glycogen content. The adrenals were hyperplastic and in 2 cases hyperemic.

Ammonia Defense in Experimental Acidosis. B. Herner.—p. 1924.

Perforating Gastric or Duodenal Ulcer in Vestfold District Hospital, 1936-1944.—Of the 76 patients with perforating ulcer treated during this period 74 were men and 2 women, with the average age of 43. An increase in perforating ulcer occurred during the war. Saxholm states that resection is well borne by patients with perforation and gives better results than other operative methods. Resection was done in 64, suture in 11, suture and gastroenterostomy in 1. There were 10 deaths. The late results in 49 patients observed for from nine months to nine years show 27 well, 21 improved and 1 not improved; the results are better than the figures indicate, many patients classified as improved being on the borderline of cured. Because of the war information was not available on 17 patients. The mortality after resection was 6.2 per cent, while after 379 resections during the same period in ordinary ulcer without acute complications it was 4.7 per cent.

Book Notices

Neurosyphilis. By H. Houston Merritt, A.B., M.A., M.D., Professor of Clinical Neurology, College of Physicians and Surgeons, Columbia University, New York, Raymond D. Adams, M.A., M.D., Neuropathologist and Visiting Neurologist, Boston City Hospital, Boston, and Harry C. Solomon, B.S., M.D., Professor of Psychiatry, Harvard Medical School, Boston. Cloth. Price, $11. Pp. 443, with 58 illustrations. Oxford University Press, 114 5th Ave., New York 11, 1946.

This textbook on neurosyphilis is written from the interrelated points of view of the neurologist, neuropathologist and psychiatrist. The clinical and pathologic material on which it is largely based has been drawn from the three authors' extensive experiences at the Boston City Hospital and the Boston Psychopathic Hospital. Various sections of the book cover the clinical and pathologic aspects of the several types of neurosyphilis thoroughly and in logical sequence. Certain syndromes, e. g. syphilitic spinal spastic paraplegia (Erb), merit a more detailed consideration. Complete correlation between the clinical manifestations and the histopathology of such diverse syndromes as tabes dorsalis, dementia paralytica and the multiform lesions of meningovascular neurosyphilis is as yet not possible, but Merritt, Adams and Solomon have more closely approximated the correlation than have other authors lacking their combined breadth of view. The therapy of neurosyphilis is less adequately summarized. Notably lacking is any evaluation of the Dattner-Thomas concept of cerebrospinal fluid "activity" as determined by the cell counts and protein determinations. The usefulness of penicillin in the various syndromes of syphilis of the central nervous system is briefly discussed. This drug has proved to be less efficacious in primary optic atrophy than the authors' early experience suggested, but the prediction that "in paretic and possibly in other types of parenchymal neurosyphilis penicillin will be found to be most efficacious when used in conjunction with therapeutic fever" now appears to have been well grounded. Those interested in neurosyphilis and in the intricacies of neuropsychiatric diagnosis will find this a book of significant value.

Heredopathia atactica polyneuritiformis: A Familial Syndrome not Hitherto Described. A Contribution to the Clinical Study of the Hereditary Diseases of the Nervous System. By Sigvald Refsum. Translated from Norwegian by Claude Lillingston, M.D. Paper. Pp. 303, with 28 illustrations. Johan Grundt Tanum Forlag, Oslo; Mercators Tryckeri, Helsingfors, 1946.

During 1937-1943 an unusual syndrome was presented by 4 Norwegian patients who belonged to two different families and were treated in the neurological department of the Rikshospital. They presented an unusual syndrome and had previously been referred to at a neurologic demonstration at the Rikshospital in Oslo on June 7, 1944 at a staff meeting and at the ninth Congress of Scandinavian Neurologists on Sept. 23, 1945 at Stockholm. A short preliminary communication was published in *Nordisk Medisen.* The clinical picture has been mentioned by Professor Monrad Krohn in the Text Book of Internal Medicine, volume v, under the term "heredopathia atactica polyneuritiforms (Refsum)." As far as the author can ascertain, the familial syndrome has previously not been described.

The syndrome consists of hemeralopia, which occurred in all 5 patients, and atypical retinitis pigmentosa, which occurred in all 3 members of family B. In the 2 patients of family A the fundus could not be viewed adequately because of miosis. These 2 patients had concentric limitation of the field of vision in addition to hemeralopia. The syndrome is also characterized by a condition suggestive of chronic polyneuritis (decreased to absent deep reflexes), reduced position and vibration sense, deep muscle tenderness, inconstant superficial sensory signs, pains, paresthesias and ataxia mainly cerebellar in type and other cerebellar phenomena. Changes began in adult life and were insidious. Hemeralopia and visual field changes preceded disturbances of gait by years. One patient noticed remissions in periods of rest. Treatment was of no value, although in 1 patient there was a question of some objective improvement. There were no mental changes.

Three of the patients presented definitely pathologic electrocardiograms. Three of the patients presented sinus tachycardia. In the fifth case, death occurred suddenly and no electrocardiogram was performed. Both patients of family A died of suggestive respiratory paralysis. The cerebrospinal fluid of 3 patients showed an albuminocytologic dissociation with a normal cell count and a great increase of protein. Three patients had abnormal pupils. Two patients suffered from a neurogenic impairment of hearing. Two patients of family A showed symmetrical epiphysial dysplasia in the elbow, shoulder and knee joints.

Clinical analysis indicates a relationship to the heredoataxias and progressive neural amyotrophy. It is considered hereditary, possibly a simple recessive mode. Postmortem examination of 2 patients of family A suggests that the pathologic findings resemble the lipoidoses such as Niemann-Pick disease and familial amaurotic idiocy. Each case record is given in detail and then summarized. The symptomatology in general is then summarized. There is a detailed differential diagnosis with a bibliography of 817 references. The general summary is also in French and German. Further recognition and pathologic study of additional cases will prove this syndrome as a definite entity. From the genetic point of view it should be recognized to prevent its propagation.

Practical Handbook of the Pathology of the Skin: An Introduction to the Histology, Pathology, Bacteriology and Mycology of the Skin with Special Reference to Technique. By J. M. H. MacLeod, M.A., M.D., F.R.C.P., Physician and Hon. Director of the Pathological Department, St. John's Hospital for Diseases of the Skin, London, and I. Muende, M.R.C.P., M.B., B.S., Physician with charge of Pathological Department and Lecturer at St. John's Hospital for Diseases of the Skin, London. Third edition. Cloth. Price, $10.50; 50s. Pp. 415, with 152 illustrations. P. B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33d St., New York 16; H. K. Lewis & Co., Ltd., 136 Gower Street, London, W. C. 1, 1946.

The authors' purpose is more accurately described by the subtitle. The book deserves special recommendation for the clarity and balance used in presenting difficult technical subject matter. The more common diseases, as eczema, psoriasis and epithelioma, are discussed fully, while the authors fortunately resisted the temptation to dwell at length on rare conditions with bizarre pathologic pictures. Emphasis is placed on the mechanism of pathologic changes—on pathologic changes in motion as it were—and these changes are skilfully correlated with clinical findings. The book contains thirty-seven short chapters dealing with all phases of the subject. There are notes on the object and technic of biopsies, the preparation of sections and stains, embryology and the normal histology of the skin. The pathologic changes are considered as they affect the separate layers of the skin and its special structures and appendages: the blood vessels, hair, sweat glands and pigment. The pathologic changes are considered usually in the light of differential diagnosis. The section on vesicles, for instance, describes them as they occur in eczema, dyshidrosis, miliaria, scabies, varicella, herpes and pemphigus. Hyperkeratoses, edemas, dystrophies, atrophies and other pathologic states are similarly considered and so give a better comprehension of the various clinical pictures. In addition, the book also contains material of a type usually found in works on clinical pathology, such as methods for examining scales and blood smears and for the identification of various fungi and parasites that attack the skin. There are numerous well chosen illustrations in the form of drawings and photomicrographs, many of them in color. The book is well indexed. Altogether this is a simplified, well written, practical handbook that should be useful to both medical students and practitioners.

Pharmacy's Part in Society. By George Urdang, Ph.G., D.Sc.Nat., Sc.D. Cloth. Price, $1.05. Pp. 93, with illustrations. American Institute of the History of Pharmacy, Pharmaceutical Library, 457 Chemistry Building, Madison, Wisconsin, 1946.

This volume presents a brief historical sketch of the contributions of the science of pharmacy to the health and culture of the people of the world. Emphasis is placed on the scientific contributions of a number of famous members of the pharmaceutical profession to chemistry, botany, agriculture and medicine. The book is attractively printed and lavishly illustrated and should prove of interest to historically minded physicians and pharmacists.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF ARTERIOSCLEROTIC LEG

To the Editor:—Please discuss the treatment of a man aged 60 with moderately severe diabetes mellitus which is under excellent control. The patient has inadequate circulation of the foot, with an ulcer of the ankle. X-ray examination reveals extensive calcification of the posterior tibial vessel. Is there any way to decalcify this vessel?

M.D., New Mexico.

ANSWER.—Chronic ulcer at the level of the ankle in a man aged 60 afflicted with diabetic arteriosclerosis is apt to be due to the obliteration of arteries and probably the arterioles of the lower extremity. Often venous stasis or deep thrombophlebitis may be additional factors. Presuming that not only the blood sugar but the blood cholesterol is under sufficient control, the problem resolves itself into increasing circulation to the affected area. If the ulcer is infected, dressings with penicillin solution or jelly are helpful. Rest in bed for several weeks is important. If the foot and ankle are moist and cold but can be warmed up by a heat cradle on the abdomen, sympathetic activity can be abolished by paravertebral injections of procaine. Lumbar ganglionectomy is safe, simple and quite effective in experienced hands and if vascular involvement elsewhere, such as in the heart, kidneys or brain, is not prominent. If there is evidence of diabetic neuritis with intermittent "lancinating" pain, peripheral nerve crushing is of some benefit. Intermittent venous hyperemia produced by a blood pressure cuff and used by the patient himself is useful in suitable cases. Amputation may be inevitable if the leg remains intractably painful, if it is wholly useless or if ascending infection develops. The responsibility of directing treatment should be shared by the family physician and a consultant. The calcified vessels can neither be canalized nor decalcified, and only by increasing the caliber and number of collateral vessels can improvement be expected.

B. SUBTILIS IN VAGINAL CULTURES

To the Editor:—A woman aged 32 has been complaining of a profuse, persistent vaginal discharge of many years' duration. Repeated cultures of the discharge revealed only Bacillus subtilis. Please discuss treatment.

M.D., Maine.

ANSWER.—Bacillus subtilis is usually a contaminant. There are many causes for discharge from the vagina in a woman aged 32. These conditions include vaginal trichomoniasis, vaginal mycoses, foreign body in the vagina, cervicitis and excessive cervical secretion. Ordinarily cultures of vaginal discharge are a less satisfactory way of establishing a diagnosis because rarely will one find a single organism. There may be a great preponderance of one organism, but if one uses proper mediums and both aerobic and anaerobic cultural technics one should find several different types of bacteria. It is suggested that a careful study be made of a hanging drop and of a direct smear (stained by Gram's method). The treatment of course will depend on what is actually causing the condition. A thorough inspection of the cervix should be made. The cervix may be the primary focus even though there is some vaginitis. There is no good evidence incriminating B. subtilis as the offending organism. Hence further study is necessary either to establish this point or to arrive at a proper diagnosis.

MARRIAGE OF FIRST COUSINS

To the Editor:—A young couple desire to be married but fear to do so because they are first cousins. Careful questioning has failed to disclose any history of congenital deformity, epilepsy, diabetes, tuberculosis or nervous and mental disorders in any member of the family in the past two generations. The parties involved present no physical or psychiatric problems. Under these circumstances should there be any fear of unhealthy offspring as a result of this union?

M.D., California.

ANSWER.—Most geneticists believe that there is no biologic objection to marriage of first cousins, if no undesirable inherited traits or extremes of personality occur in that part of the ancestry which they have in common. Ordinarily knowledge of the two preceding generations is sufficient to establish the facts.

POSSIBLE PSEUDOHEMOPHILIA

To the Editor:—A white boy aged 11 years, of Italian descent, has had recurrent severe epistaxis since infancy. His mother had the same condition but was relieved by operation on the nose. The nature of the operation is unknown. The boy has had nasal cauterization innumerable times with temporary relief. Physical examination, including examination of the nose, is negative. The only positive finding is an absence of clot retraction after twenty-four hours, with only negligible retraction after forty-eight hours. All other blood studies are within normal limits. There are no petechiae on the antecubital skin after fifteen minutes at a pressure of 85 mm. Hemorrhage stops with local application of ceanothyn but forms large clots which obstruct breathing. At the present time the patient is receiving ascorbic acid 75 mg. daily and rutin 20 mg. three times daily. Does this case fit the description of any of the lesser known blood dyscrasias? What treatment is suggested?

Robert E. Sinderbrand, M.D., Egg Harbor City, N. J.

ANSWER.—In the patient as described in the query two or more tests should be made of the coagulation time of venous blood (Lee-White method), bleeding time (both the Duke and Ivy methods), platelet count, clot retractility, prothrombin time, plasma fibrinogen and capillary fragility. The normal blood clot occasionally fails to retract unless loosened from the walls of the tube by a platinum wire.

In 1918 Glansmann (*Jahrb. f. Kinderh.* **88**:1 and 113) reported cases of a familial hemorrhagic diathesis characterized by a poor or incomplete clot retractility and a normal bleeding time, coagulation time and platelet count. He thought the condition was related to a platelet defect and called it hereditary hemorrhagic thrombasthenia. Similar cases have not been reported.

Von Willebrand (*Arch. f. klin. Med.* **17**:453, 1933) later described a syndrome which he designated as pseudohemophilia. The disease was hereditary and was associated with a tendency to bleed. Epistaxis was common. The bleeding time was regularly prolonged, but the coagulation time, platelet count and clot retractility were normal. Sixty-two cases from the literature meeting these criteria have been recently analyzed by Estren, Médal and Dameshek (*Blood* **1**:504 [Nov.] 1946) and they added 11 cases of their own. The clot retractility was abnormal in 6 out of 61 cases in which the test was performed. Somewhat less than half of the cases showed increased capillary fragility.

It is possible that the case in the query as well as other cases of familial epistaxis reported in the literature fall into the category of pseudohemophilia. The absence of visible lesions in the nose and the abnormality of the clot retraction are against the diagnosis of hereditary hemorrhagic telangiectasia.

There is no effective treatment for this condition. Nasal hemorrhage often can be controlled by the application of thrombin soaked gauze or of thrombin-fibrin foam. Blood transfusions usually have no effect on the bleeding but should be given for anemia resulting from hemorrhage.

CEREBRAL HEMORRHAGE AND MUSCULAR EXERTION

To the Editor:—A man aged 40 with known hypertension lifted a heavy object while working at his usual occupation. He was seized with unsteadiness, lapsed into a coma and died within an hour. The cause of death was given as arterial hypertension and massive cerebral hemorrhage. Is it fair to say that the effort involved in the lifting of the heavy object precipitated a rupture of a cerebral vessel previously damaged by arteriosclerosis or is it the present consensus that such an accident was purely fortuitous?

M.D., Connecticut.

ANSWER.—With hypertension and cerebral arterial disease a cerebral hemorrhage may occur at any time without relationship to any effort or activity. As far as we know, hemorrhage is usually the end result of progressive disease uninfluenced by any temporary rise in blood pressure.

Blood pressure is temporarily raised by the lifting of a heavy object. It is logical to expect that such a rise in pressure increases the possibility of hemorrhage. If it does so, then the hemorrhage will take place during the time the pressure is raised. The increase in pressure from a lifting effort disappears immediately on cessation of the effort, so that any effect of the effort must ensue immediately. The assumption of cause and effect seems rational.

Logical though it may be, causal relationship of so common a condition cannot be accepted without examination in the light of clinical observation of a series of cases. Clinically, the evidence is not strong that cerebral hemorrhage is distinctly more common during effort than when the patient is at rest. However, most observers believe that hemorrhage is more frequent during sneezing, straining at stool and on muscular effort than can be ascribed to coincidence. These are activities that cause a temporary physiologic rise in blood pressure. Considering the data we must conclude that it is probable that in the case described in the query the lift was a factor in precipitating the hemorrhage.

SECTION OFFICERS 1946-1947

Internal Medicine—Chairman, Joseph T. Wearn, Cleveland; Vice Chairman, Roy H. Turner, New Orleans; Secretary, Cecil J. Watson, 412 Delaware Street S.E., Minneapolis.

Surgery, General and Abdominal—Chairman, Alton Ochsner, New Orleans; Vice Chairman, John B. Flick, Philadelphia; Secretary, Michael E. deBakey, 1430 Tulane Ave., New Orleans 13.

Obstetrics and Gynecology—Chairman, Alice F. Maxwell, San Francisco; Vice Chairman, Robert J. Crossen, St. Louis; Secretary, William F. Mengert, 2211 Oak Lawn, Dallas, Texas.

Ophthalmology—Chairman, Derrick Vail, Chicago, Vice Chairman, Warren D. Horner, San Francisco; Secretary, Robert J Masters, 23 East Ohio Street, Indianapolis.

Laryngology, Otology and Rhinology—Chairman, J. Mackenzie Brown, Los Angeles, Vice Chairman, Carl H. McCaskey, Indianapolis; Secretary, Fletcher D. Woodward, 104 East Market Street, Charlottesville, Va.

Pediatrics—Chairman, Gilbert J. Levy, Memphis, Tenn.; Vice Chairman, Charles A. Weymuller, Brooklyn; Secretary, Margaret Mary Nicholson, 1801 Eye Street N.W., Washington, D. C.

Experimental Medicine and Therapeutics—Chairman, Carl A. Dragstedt, Chicago, Vice Chairman, Walter Bauer, Boston; Secretary, Dwight L. Wilbur, 490 Post Street, San Francisco.

Pathology and Physiology—Chairman, J. J. Moore, Chicago; Vice Chairman, Alvin G. Foord, Pasadena, Calif.; Secretary, Frank W. Hartman, 2799 West Grand Boulevard, Detroit.

Nervous and Mental Diseases—Chairman, R. P. Mackay, Chicago; Vice Chairman, Louis J. Karnosh, Cleveland; Secretary, Fred P. Moersch, 102 Second Avenue, S.W., Rochester, Minn.

Dermatology [illegible] Nelson Paul Anderson, Los Angeles; Vice Chairma [illegible] York; Secretary, Clinton W. Lane, 508 North Grand

Preventive and Industrial Medicine and Public Health—Chairman, Clarence O. Sappington, Chicago; Vice Chairman, R. H. Riley, Baltimore; *Secretary*, Rutherford T. Johnstone, 727 West Seventh Street, Los Angeles.

Urology—Chairman, Grayson L. Carroll, St. Louis; Vice Chairman, Clark M. Johnson, San Francisco; Secretary, Edward N. Cook, 102 Second Avenue, S.W., Rochester, Minn.

Orthopedic Surgery—Chairman, Francis M. McKeever, Los Angeles; Vice Chairman, J. Warren White, Greenville, S. C.; Secretary, Joseph S. Barr, 234 Marlborough Street, Boston.

Gastro-Enterology and Proctology—Chairman, Martin S. Kleckner, Allentown, Pa.; Vice Chairman, Sara M. Jordan, Boston; Secretary, Grant H. Laing, 104 South Michigan Boulevard, Chicago.

Radiology—Chairman, Bernard P. Widmann, Philadelphia; Vice Chairman, W. Walter Wasson, Denver; Secretary, U. V. Portmann, 2020 East 93d Street, Cleveland.

Anesthesiology—Chairman, Charles F. McCuskey, Los Angeles; Vice Chairman, Harry Boyd Stewart, Tulsa, Okla.; Secretary, John S. Lundy, 102 Second Avenue S.W., Rochester, Minn.

General Practice of Medicine—Chairman, Paul A. Davis, Akron, Ohio; Vice Chairman, E. A. Royston, Los Angeles; Secretary, W. B. Harm, 5884 West Vernor Highway, Detroit.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY—APRIL 1947

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1936. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," *Bureau of Investigation*; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1369.
